reported to be afflicted with trachoma. Detail for the board: Passed Assistant Surgeon M. W. Clover, chairman; Assistant Surgeon C. W. Chapin; Acting Assistant Surgeon F. R. Underwood, recorder.

### Army Intelligence:

*Official list of changes in the stations and duties of officers serving in the medical department of the United States Army for the week ending March 21, 1908:*

**BIRMINGHAM, H. P.**, Major and Surgeon. Having reported in compliance with paragraph 2, S. O. 54, War Department, March 5, 1908, is announced as chief surgeon, Army of Cuban Pacification, relieving Lieutenant Colonel Clair D. Taylor, deputy surgeon general.

**ROBERTS, W. M.**, Captain and Assistant Surgeon. Ordered to Fort Hancock, N. J., for duty.

**SCHREINER, E. R.**, Captain and Assistant Surgeon. Ordered to report to the commanding officer, Headquarters Band, First and Third Battalions, Twenty-fourth Infantry, San Francisco, Cal., for duty to accompany that command en route to Madison Barracks, N. Y., and upon completion of this duty to return to his proper station.

**SHEPARD, J. L.**, Captain and Assistant Surgeon. Now on leave of absence, will proceed on or before the expiration of said leave to Fort Sam Houston, Tex., for duty at that station.

### Navy Intelligence:

*Official list of changes in the medical corps of the United States Navy for the week ending March 21, 1908:*

**BACON, S.** Detached from duty at the Naval Medical School, Washington, D. C., and ordered to report to the president of the naval examining board, Washington, D. C., April 1, 1908, for examination for appointment as an assistant surgeon, and then to await orders.

**BIELLO, J. A.**, Acting Assistant Surgeon. Detached from duty at the naval medical examining board, Washington, D. C., and ordered to report to the president of the naval medical examining board, Washington, D. C., April 1, 1908, for examination for appointment as an assistant surgeon, and then to await orders.

**DE LANCY, C. H.**, Passed Assistant Surgeon. Detached from the Navy Yard, New York, N. Y., and ordered to duty in connection with fitting out the *Newark*, and to duty on board that vessel when commissioned.

**GARRISON, H. A.**, Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to the Naval Hospital, Philadelphia, Pa.

**HAINES, B. F.**, Acting Assistant Surgeon. Detached from duty at the Naval Medical School, Washington, D. C., and ordered to report to the president of the naval medical examining board, Washington, D. C., April 1, 1908, for examination for appointment as an assistant surgeon, and then to await orders.

**HIGGINS, M. E.**, Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to duty at the Naval Training Station, San Francisco, Cal.

**HOLEMAN, C. J.** Detached from the Naval Medical School, Washington, D. C., and ordered to duty at the Naval Training Station, San Francisco, Cal.

**HOUGH, F. W. P.**, Acting Assistant Surgeon. Detached from duty at the Naval Medical School, Washington, D. C., and ordered to report to the president of the naval examining board, Washington, D. C., April 1, 1908, for examination for appointment as an assistant surgeon, and then to await orders.

**MCGUIRE, L. W.**, Acting Assistant Surgeon. Detached from duty at the Naval Medical School, Washington, D. C., and ordered to report to the president of the naval examining board, Washington, D. C., April 1, 1908, for examination for appointment as an assistant surgeon, and then to await orders.

**MORGAN, C. R.**, Acting Assistant Surgeon. Detached from duty at the Naval Medical School, Washington, D. C., and ordered to report to the president of the naval medical examining board, Washington, D. C., April 1, 1908, for examination for appointment as an assistant surgeon, and then to await orders.

**MILLER, J. T.**, Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to duty at the Naval Medical School, Washington, D. C., and ordered to report to the president of the naval medical examining board, Washington, D. C., April 1, 1908, for examination for appointment as an assistant surgeon, and then to await orders.

**MORGAN, C. R.**, Acting Assistant Surgeon. Detached from duty at the Naval Medical School, Washington, D. C., and ordered to report to the president of the naval medical examining board, Washington, D. C., April 1, 1908, for examination for appointment as an assistant surgeon, and then to await orders.

**OHNESONG, K.**, Surgeon. Detached from duty at the Naval Hospital, Philadelphia, Pa., and ordered to the Navy Yard, League Island, Pa., for duty in connection with fitting out the *New Hampshire*, and for duty on board that vessel when placed in commission.

**PLUMMER, R. W.**, Passed Assistant Surgeon. Detached from the Naval Recruiting Station, Chicago, Ill., March 30, 1908, and ordered to Washington, D. C., April 1, 1908, for examination for promotion, and then to await orders.

**RHOADES, G. C.**, Acting Assistant Surgeon. Detached from duty at the Naval Medical School, Washington, D. C., and ordered to report to the president of the naval examining board, Washington, D. C., April 1, 1908, for examination for appointment as an assistant surgeon, and then to await orders.

**SNYDER, J. J.**, Passed Assistant Surgeon. Detached from the Naval Hospital, Philadelphia, Pa., and ordered to instruction at the Naval Medical School, Washington, D. C.

**VERNER, W. W.**, Passed Assistant Surgeon. Detached from the Naval Training Station, San Francisco, Cal., and ordered to duty in connection with fitting out the *Wisconsin*, and to duty on board that vessel when commissioned.

**WILLIAMS, R. B.**, Passed Assistant Surgeon. Detached from the *Franklin* and ordered to the Naval Hospital, Philadelphia, Pa.

## Births, Marriages, and Deaths.

### Born.

**KIERULFF.**—In San Francisco, California, on Friday, February 28th, to Dr. H. Newton Kierulff, United States Army, and Mrs. Kierulff, a daughter.

### Married.

**CAREY—MILLER.**—In Philadelphia, on Tuesday, February 18th, Dr. H. M. Carey, of St. Georges, Delaware, and Miss Minnie E. Miller, of Pomona, Kansas.

### Died.

**BRYANT.**—In Boston, on Friday, March 20th, Dr. John Bryant, aged forty-seven years.

**BYSFIELD.**—In St. Louis, Missouri, on Monday, March 16th, Dr. Frank B. Byfield, aged sixty years.

**CANNON.**—In Lawrenceburg, Kentucky, on Wednesday, March 11th, Dr. F. M. Cannon, of Oxford, Scott County, aged seventy-six years.

**DEVLIN.**—In Denver, Colorado, on Saturday, March 14th, Dr. James B. Devlin, aged fifty-six years.

**EATON.**—In Philadelphia, on Tuesday, March 17th, Dr. William Bradford Eaton, aged thirty-nine years.

**LAMB.**—In Chicago, on Wednesday, March 11th, Dr. Orin C. Lamb, aged sixty-eight years.

**LANGREHR.**—In Philadelphia, on Sunday, March 15th, Dr. Hiram Langrehr, aged sixty-eight years.

**NICKELS.**—In Sellersburg, Indiana, on Thursday, March 12th, Dr. John M. Nickels, aged sixty years.

**NINDE.**—In Colonial Beach, Westmoreland County, Virginia, on Tuesday, March 10th, Dr. Frederick F. Ninde.

**PETTIT.**—In New Orleans, Louisiana, on Monday, March 16th, Dr. Absalom Pettit, aged sixty-eight years.

**ROGERS.**—In Charlottesville, Virginia, on Sunday, March 15th, Dr. William G. Rogers, aged eighty-six years.

**ROWLAND.**—In Atlanta, Georgia, on Tuesday, March 10th, Dr. Anak A. Rowland, aged seventy-four years.

**SCARFF.**—In Govans, Maryland, on Wednesday, March 11th, Dr. John H. Scarff, aged fifty-seven years.

**SCHPEPERS.**—In Chicago, on Wednesday, March 11th, Dr. D. Q. Schpepers.

**TOTTEN.**—In Cleveland, Ohio, on Monday, March 16th, Dr. Roy O. Totten.

**WILSON.**—In Washington, D. C., on Friday, March 13th, Dr. Anne A. Wilson.

**WYCKOFF.**—In Trenton, New Jersey, on Thursday, March 19th, Dr. William A. Wyckoff, aged seventy-one years.

#### WHAT WE HAVE NOT DONE FOR THE INSANE.\*

BY FREDERICK PETERSON, M. D.,  
New York,

Former President of the New York State Commission on Mental Diseases,  
Professor of Psychiatry, Columbia University.

It is a wonderful catalogue of achievement for the welfare of the insane that Dr. MacDonald has outlined this evening. New York now leads the States in its provisions for the insane. I, too, bear witness to how much has been accomplished in less than twenty years by the Lunacy Commission, the superintendents and managers of the hospitals, and the State Charities Aid Association.

But, as with most human undertakings, there is still a higher standard to which we must aspire. Let us not be too easily satisfied. There are defects to remedy, and ideals to attain, and I feel it my duty to point out as briefly as possible some of these defects and these ideals. We could fill a book with praise for what has been accomplished, but we might also fill a book with criticism of conditions as they are. The people having assumed the burden of State care are bound to be interested in all that pertains to it, in the conditions that lead to the asylum, in prophylaxis, in the care of the patient before admission to the hospital, in the hospital conditions themselves, and in the after care of the convalescent and recovered insane.

What are we doing for prophylaxis? There are several preventable causes of insanity. It has been estimated that nearly 20 per cent. of the insane under State care owe their insanity to alcohol, a preventable cause. That is nearly 6,000 patients in this State in round numbers. Dr. MacDonald has just told us that one insane person means an approximate loss to the State of \$400 per annum. Surely the people of the State have an interest in this \$2,400,000 annual loss to the State through alcoholic insanity. The asylum physicians in each hospital district should be the leaders in a campaign of education for the regions round them. They could preach prophylaxis understandingly, and they are able to open outdoor clinics in connection with each hospital, where free advice and treatment might be extended to the poor insane in the early stages before commitment becomes necessary.

Owing partly to the prisonlike plan on which the older asylums were built, and partly to the complicated judicial procedure necessary for the

commitment of patients, there still exists among the people an ancient legacy of feeling about an asylum, and they pass it as they do a prison or a cemetery, with mixed dread and mistrust. Out of this, too, they must be educated. Though we exchanged the word asylum for the word hospital, we have not yet succeeded in instilling into the minds of the public that the insane are sick. They must learn that insanity is an illness, a preventable and curable one. When this is once learned they will never again permit the acutely insane to be taken to jails and station houses, as they are at the present time frequently all over this State, pending commitment to a hospital for the insane. They will provide psychopathic hospitals in all of our larger cities or pavilions in connection with general hospitals (as at Bellevue Hospital in New York, Kings County Hospital, Brooklyn, and the General Hospital, in Albany), to which all emergency cases of insanity can be taken for observation and treatment before transfer to hospitals for the insane. The period of detention in such general hospitals or psychopathic hospitals should be at least ten days, instead of five days, and without any magistrate's or judge's order whatever. This is a purely medical and not a legal matter. It is a question for a board of health to regulate, not the courts. As Dr. Meyer has suggested to me, it should fall altogether under the rules of quarantine. An insane person is sick, and is a menace to himself and the public while thus sick. If we can restrain a person of his liberty without commitment papers when he has diphtheria and other contagious or infectious diseases, why have recourse to a judicial proceeding in emergency cases of insanity? If physicians unite in demanding the recognition of insanity as a disease this point will be gained. Of course for longer stays in hospitals and retreats for the insane a regular form of commitment is necessary for the protection of the sane. But chartered general hospitals should be permitted to receive and treat cases of insanity for whatever length of time is expedient, and all hospitals and retreats for the insane should be permitted to receive, on the recommendation of any physician or relative, emergency cases of insanity for a ten-day period for observation and treatment pending commitment.

After the patients have been admitted to the hospitals what conditions do they find there that are unsatisfactory? In the first place, I should mention overcrowding. The Lunacy Commission reports overcrowding every year. The responsibility for its continuance rests with the legislature, and

\*The subject of this paper was discussed at the meeting of the Academy of Medicine, February 22, 1908.

there responsibility is so finely divided that it is practically nothing at all. It is like some of the smaller currency of India, which Mark Twain says is so attenuated that you can give nothing and get nothing for it. With an addition of nearly one thousand patients a year it means that we ought to build practically a new hospital for the insane annually. It means an expense of at least \$600,000 annually for new accommodations. Only one new hospital for the insane has been established and constructed by the State in eighteen years. Some additions are made every year, but they are never adequate, and such additions are made to existing asylums until they are growing unwieldy. Three of our asylums are already probably the largest in the world. In the report of the Lunacy Commission for October, 1906, the excess of patients in the hospitals over the estimated capacity was 1,812. But the estimated capacity in itself has always been forced far beyond what it ought to be. It is forced some 20 per cent. above what it ought to be. To estimate such capacity every available space for a bed is utilized. Hallways, day rooms, and corridors are used for dormitories. Single rooms intended for one patient are made to accommodate two or even three. Beds are placed side by side in dormitories, so that patients are compelled often to climb over the foot of the bed to get into it. Even were the 1,812 excess not there, there would still be overcrowding. The overcrowding on Ward's Island is said to be 30 per cent. above capacity, and some 2,000 of New York city's insane are scattered about the State in various other hospitals, even as far off as Buffalo and Gowanda.

Of course the first remedy for this state of affairs that suggests itself is that the money be appropriated at once for the construction of new asylums. But there are other ways of reducing the hospital population. A great part of the accommodation in the asylums is due to admission of old people. Some 16 to 17 per cent. of the admissions are people between sixty and one hundred years of age. A considerable proportion of these are not insane. They are physiologically senile or dotards. In the struggle for life among the poor, old people are a burden, especially when they become decrepit and feeble in mind. When the State Care Act went into effect, the relatives soon found that the State hospitals were better by far for the aged and infirm dependents than the notorious almshouses. Hence by all manner of subterfuge the senile have been certified as insane, and help to swell the hospital population. Doubtless if the State could help the sons or daughters to the extent of paying the actual cost to the State of the board of such patients, now about \$172 per year, a very large proportion of these aged people would be taken back to their own homes. This would not only be better in some respects for the senile patients, but more satisfactory to the relatives. It would be, in a way, inaugurating the boarding out system, which has been so successful in Scotland, where nearly 3,000 patients are boarded out in private families, a considerable proportion with their own relatives. If it were begun with the senile, the same principle might be extended to other

classes. The scheme has been in successful operation in Massachusetts for many years.

Besides being overcrowded, the State hospitals are inadequately supplied with physicians. Many years ago the physicians were in the proportion of 1 to 128 patients. Since the State undertook the care of the insane, the proportion has fallen, partly for economy's sake (the cost of all physicians' services being \$8 to \$10 a year, or 3 cents a day for a patient) and partly through difficulty in securing medical men to fill vacancies, to the present figure of 1 to 174. The proportion should be much larger, at least 1 to 150.

The number of nurses and attendants is also inadequate, and there is great difficulty in obtaining even a sufficiency of inferior individuals to fill vacancies in some of our asylums. The wages should be made high enough to attract a better class, and the training school system, which has done so much good, needs extension, and ought to be put under some competent superintendent of nurses as in general hospitals.

While recreations and occupations for patients have been multiplied and improved upon to a great degree in the State hospitals, this is still a form of psychotherapy that is far from sufficiently developed. It is probably the most important form of therapy for the vast majority of the patients, yet it plays a very small part, after all, in the hospital régime. Each hospital should have several employees whose sole duty should consist in keeping patients occupied in various recreative exercises, industries, and handicrafts. The exercise and occupation cure nowadays so extensively applied to various neuroses, both here and abroad, as at the Craig Colony, at Dr. Hall's place at Marblehead, and at Dr. Sharp's at Katonah, should be carried out quite as elaborately, and really with more reason, at every hospital for the insane.

Thus far I have been discussing conditions in the State hospitals. When we take up the matter of the twenty-two private retreats for the insane in the State of New York, we find that while there has been some advance on the whole in the methods and manner of care, there is still much to be desired. In fifty per cent. perhaps of the twenty-two institutions the standard of care is scarcely equal to that of the State hospitals. There is not the same painstaking, scientific study of the cases, not the same alert medical spirit, not the same ambition to excel and progress, and no systematic occupation of patients, such as would be easily possible in an institution of small size with considerable income. One would think that with such abundant leisure and select material, substantial contributions to science might emanate from these smaller institutions, and that instead of lagging behind the great State institutions they would be in the van, in the lead, and point the way to further advance in psychiatry and in methods of treatment and care. This has been possible to one private institution in America at least, the McLean Hospital at Waverley, Mass.

And now a few words as to the after care of the convalescent and recovered insane. Within two or three years, chiefly through the efforts of Miss Louisa Lee Schuyler, of the State Charities Aid

Association, an after care organization has been founded, and already some good work accomplished in connection with several of the State hospitals. This work should be extended to all parts of the State, and it should include among its functions forecare or prophylaxis as well as after care. The hospital physicians themselves should be the most active members of such a body, because of the opportunities thus afforded for the better study of the conditions under which the mental disorders have arisen, because they may thus secure fuller histories of their patients, both before admission and after discharge, and in order to more clearly understand and disseminate the facts in relation to prophylaxis.

4 WEST FIFTIETH STREET.

### GENERAL SURGICAL CONSIDERATIONS OF JOINT AND BONE TUBERCULOSIS.\*

By JOSEPH WIENER, M. D.,  
New York,

Adjunct Attending Surgeon, Mt. Sinai Hospital.

**Diagnosis.**—The diagnosis is made from the family history, the previous history of the patient, the examination of the entire body, and the use of the x ray. In doubtful cases tuberculin may be injected, both for the local and for the general reaction. In children, the new method of dropping tuberculin in the eye, by which we obtain a local reaction within eight hours, is free from danger of lighting up an old focus [Calmette reaction]. Occasionally the aspiration of a joint, together with animal inoculation, will be of service. The distinctive diagnosis must be made from lues, acute osteomyelitis, and arthritis. In acute osteomyelitis the sudden onset, high fever, marked prostration, and high leucocyte count will make the diagnosis. In lues, antilutetic treatment will clear up the diagnosis. Tuberculosis of the joint may, secondarily, infect the shaft of the bone; and, conversely, the primary infection of the bone may secondarily infect the joint. Sometimes, especially about the knee, it is difficult, even at operations, to determine where the primary focus was.

The hip and knee make up forty per cent. of all cases of bone and joint tuberculosis. These joints must carry the weight of the body, and they are more prone to injury than other joints. As in other tuberculous lesions, predisposition plays a great rôle. To this must be added poor housing, poor nourishment, and debilitating sickness of any kind.

Advanced tuberculosis of the joint may lead to subluxations; at times, especially in the hip, a dislocation may result from a slight injury. Owing to disuse of a joint, the neighboring muscles atrophy, and there is often a contracture of the muscles, particularly cicatricial, partly nutritive. In advanced cases, where an entire extremity falls into disuse, all the muscles of that extremity are thus affected. Even the blood-vessels are involved. Lannelongue has pointed out that the femoral artery and its large branches are often decreased in diameter in cases of tubercular hip.

**Prognosis.**—The prognosis varies with the joint

that is affected, and with the degree of infection. In the hip a cure, so called, will often be followed, after years, by tuberculosis in other parts of the body. There is usually some shortening remaining after hip disease. In the knee there is almost always some limitation of motion and some stiffness resulting. This is found in most cases, be the treatment expectant, palliative, or radical. There often remains a condition of genu valgum. The growth of the limb is often interfered with, partly by destruction of the epiphyseal centre by the disease or by operation, and partly through disuse of the limb. The amount of shortening varies with the amount of bone destroyed and with the age of the patient.

**Treatment.**—This may be divided into three parts: First, general hygienic; second, prevention of further involvement; third, direct treatment of the lesion.

1. General Hygienic.—Patients should receive fresh air day and night; they should sleep out of doors, if possible. A change of air is very beneficial. Everything possible should be done to improve the general condition, and in that way the local condition will be improved. A quiet, regular mode of living is one of the great advantages of sanatorium treatment.

2. Prevention of Further Involvement.—The *sine qua non* is absolute rest. This can be accomplished by an immobilizing dressing or by a suitable orthopaedic apparatus.

3. Direct Treatment of the Lesion.—We will not, in this paper, take up the operative treatment. The palliative treatment includes rest, orthopaedic treatment, the Bier hyperæmic treatment, the use of iodoform injections, and the use of tuberculin. Iodoform glycerin in ten per cent. solution or iodoform oil will, without any other treatment, often bring about a complete cure.

**Technique of iodoform injection.**—After rigid sterilization of the skin about the joint, a trocar and canula with a rubber tube attached are plunged obliquely into the joint in such a way that the skin opening and the opening into the joint do not directly overlie. In this way the skin overlying the joint is left intact. After evacuating the contents of the joint, the iodoform emulsion is injected through the tube attached to the canula. In young children three to four grammes, in older children eight to ten grammes, may be injected. By gentle, passive motion of the joint the emulsion can be brought into contact with the entire synovial surface. Following the injection there is generally a smart local reaction, pain, redness, swelling, and some fever. No further iodoform should be injected until all inflammatory symptoms have subsided. This will usually be in eight to ten days. A few such injections, with rest of the affected joint, will often bring about a permanent cure. Any local tuberculous abscess may be treated in this way. Fistulae may also be injected with iodoform. It may sometimes be well to follow the suggestion of Wendelstadt and insert the canula into the synovium around the *patella*. Carbolic acid, boric acid, and other similar agents have not proved as efficacious as iodoform. It is not always easy to decide in which cases to advise the iodoform injection. The greater field of usefulness is in children. In them an operative procedure about a joint

\*Read before the American Medical Society, at one of its sessions at the Hotel New York, January 1, 1908.

is only too prone to interfere with the further growth of the affected bone. And it is in children that we obtain the most brilliant functional results by the conservative treatment of bone and joint lesions. So that, in the early tuberculous joint disease the injection of iodoform is usually to be advised. However, valuable time should not be lost. If in three to four weeks there is no improvement, then some operative procedure must be undertaken. If there has not been too much delay this procedure will usually not be a severe one.

In some cases the iodoform will bring about a cure of the lesion in the joint, but there will still be some pain and tenderness around the joint. In such cases the x ray will render valuable assistance by showing a small bone focus which the iodoform could not reach, but which can be rapidly cured by a minor operation.

There is a difference of opinion as to the importance to be attached to small sequestra in bone tuberculosis. According to Riedel they occur very frequently, and he advises in all bone abscesses incision and curetting, as he believes the sequestra will prevent healing. On the other hand, Mikulicz's experience taught him that small sequestra need not be removed, as they do not interfere with the healing process.

Mikulicz regarded the Bier treatment as an adjunct of the conservative iodoform treatment. If no improvement takes place in four weeks and the process is spreading, then an open operation is indicated. But in children we should be as conservative as possible, as we often get surprisingly good functional results without extensive operations.

#### Hip.

Pain and disability are the cardinal symptoms. The former is usually the first symptom. The pain may be spontaneous or occur after prolonged exercise. In many cases the pain is chiefly nocturnal. Children in the early stages of the disease often awake at night with a sudden cry, complain of pain in the joint, and go to sleep again. The pain is probably elicited by a sudden muscular contraction. Frequently the pain from an affected hip is referred to the knee, especially on its inner side. Errors in diagnosis may thus occur. The second early symptom of hip disease is the limp. It is often the first striking symptom. The patient involuntarily drags the affected limb in order to favor the diseased joint. The limp may be constant or intermittent, usually the latter in the early stages. Besides the two cardinal symptoms of pain and limp, there is one other of great importance. If the affected limb is passively abducted or rotated ever so carefully, there will be a distinct contraction of the hip muscles. This symptom will be found present even in patients that are still able to walk quite well. By this time also the inguinal glands will usually be found enlarged. In all doubtful cases an x ray picture should certainly be taken, for, as we have mentioned above, small bone foci may be present without giving any symptoms. The x ray picture, which should include the opposite joint, will also show the presence of an exudate in the joint.

In the early stages the child favors the affected limb by bringing into play the joints of the pelvis and spine, and by not standing on the limb more

than absolutely necessary. At this time there is pain and tenderness on pressure over the joint. In the fully developed stage the limb is usually held in abduction and outward rotation and at the same time kept slightly flexed. In doubtful cases rectal examination should always be made. The examining finger will often find tenderness about the affected joint, or swelling, or even fluctuation. Swelling of the joint is due to the exudate in the joint and to a periarticular inflammatory process. A typical location of the swelling is posteriorly above the trochanter. In some cases pus develops early in the disease, in others not until the later stages. The abscess may perforate and a fistula develop on the anterior or the posterior aspect of the joint. Often the pus burrows along the abductors and perforates on the inner aspect of the thigh. Posteriorly the abscess often points at the lower border of the gluteus maximus. There is usually with the development of an abscess some rise of temperature. In most cases we cannot distinguish between a primary synovial and a primary osseous tuberculosis. Crepitation in the joint points to bone destruction, and in this stage there will usually be some shortening of the limb.

Healing can take place at any stage of the disease. In the early stages complete return of function may be expected. In later stages there will be some contraction and some limitation of motion. Still later, there will be healing, with more or less ankylosis and with shortening of the limb.

Distinctive diagnosis must be made from arthritis deformans, fracture of the neck of the femur, congenital dislocation, coxa vara, hysteria, neuralgia, articular rheumatism, spondylitis, osteomyelitis, syphilis, or gonorrhoeal infection. For some of these the x ray will help us materially in making the diagnosis. For others the distinctive diagnosis can be made from the history and general examination of the patient, and by instituting specific treatment.

*Treatment.*—Some form of extension is always indicated. This relieves the pain and prevents the limb from assuming a pathological position. For children five to fifteen pounds, for adults twenty pounds and more will be indicated. The extension separates the two ends of the bones and puts the joint at rest. Immediate relief of the pain often results. Many excellent orthopaedic splints have been devised. These, while carrying out the idea of extension, enable patient to walk about. Plaster of Paris also has a wide field. Iodoform injections are of great value. The Bier treatment is not applicable. The details of orthopaedic treatment will not be touched upon.

#### KNEE.

The synovial and osseous forms occur with equal frequency. The bone focus gives only slight symptoms, slight pain increased on pressure. It is the synovial form that we diagnosticate readily. There are three manifestations: (a) Hydrops of the joint; (b) granulation tissue formation (fungus form); (c) cold abscess of the joint.

(a) *Hydrops.*—The symptoms are similar to those of serous synovitis. The simple synovitis occurs in adults, the tuberculous in children. The spontaneous afebrile occurrence or after a slight

trauma, the chronicity of the exudate in spite of treatment, or the continued recurrence of the exudate, point to tuberculosis.

(b) *Fungus form*.—According to König, this is always preceded by hydrops of the joint. But in some cases the amount of exudate was so small as hardly to be appreciated. The thickening of the capsule is most marked in the upper part of the joint. This, together with the atrophy of the muscles, especially the quadriceps, gives the joint the characteristic spindle shape. The skin becomes thin and glossy, and the subcutaneous veins are visible. Motion of the joint becomes limited and contractures in the flexed position take place.

(c) *Cold abscess of the joint*.—This is comparatively rare, and is not to be confounded with suppuration in the fungus form. It is rarer in the knee than in the hip. Swelling of the capsule is moderate, but the synovial membrane is riddled with miliary tubercles and is lined by a pyogenic membrane which secretes a thin, purulent exudate. There is no tendency to perforation of the capsule. In doubtful cases a puncture of the joint should be made.

*Prognosis*.—Recovery can take place at any stage. The disease may last for years, and complete recovery with full mobility is very rare. We must usually be satisfied with some limitation of motion, often with ankylosis. The contractures often interfere very much with the usefulness of the limb. In children the growth of the limb is often interfered with.

*Treatment*.—The general tendency of all surgeons is toward conservatism. Any contracture should first be overcome, if necessary under anesthesia. The limb should then be put up in plaster of Paris. If complete extension is not obtained the process may be repeated in two to three weeks. If the limb cannot be straightened in this way, permanent extension for two or three weeks will usually overcome the contracture. The child can wear an orthopaedic splint which allows the weight of the body to rest on the pelvis. The knee should be kept immobilized until all pain and swelling have disappeared. For several months longer a removable splint should be worn in walking. After this long period of immobilization the joint will be quite stiff. But it is very important not to break up these adhesions too soon or too suddenly, for fear of lighting up a new inflammation. The patient will accomplish much by using the limb, and after a few months a little passive motion will help. To keep up the nutrition of the muscles massage will be found useful. *Festina lente* should be our motto in these cases.

During the period of rest of the joint, iodoform infections will be found very beneficial. Where iodoform fails, König has had good results by washing out the joint with two per cent. carbolic acid and then injecting five per cent. carbolic acid. The Bier treatment is also a valuable aid.

#### JOINTS AND BONES OF FOOT.

They are very frequently affected, usually the calcis and astragalus. The disease seldom starts in the synovial membrane. The process may spread anteriorly or posteriorly, and fistulae may form on the dorsum of the foot or on either side of the

tendo-Achillis. The first symptoms are usually a little local pain and some limp. On examination, one or more tender areas will be found. Somewhat later we find swelling around the ankle. Very seldom does the disease start with an infection of the synovial membrane.

*Treatment*.—At the onset this should be conservative. If much bone is affected, and here the x ray helps, an open operation will be necessary. Many cases, especially in children, will get well with rest, fixation, elevation of the limb, Bier treatment, and iodoform injections. If the foot is fixed, it should be at a right angle, half way between pronation and supination, so that if ankylosis takes place, the foot will be in the best possible position for walking. An ambulatory splint of plaster of Paris, similar to the one used in fracture of the leg, is very useful. Even where abscesses have developed in young subjects a cure can often be obtained without operation. If, however, the child is losing weight, or if there is a secondary infection of the soft parts, or extensive bone involvement, then an open operation is imperatively demanded. In adults we cannot hope for much from conservative treatment. The older the patient, the earlier will operation be necessary.

#### SHOULDER.

In the shoulder joint tuberculosis occurs very rarely. The age varies from fourteen to twenty years; usually the right shoulder is affected, and usually the process starts from the head of the humerus. In forty per cent. of the cases there is pulmonary tuberculosis. The disease usually spreads very slowly. As the process is chiefly in the bone, palliative measures are not of much avail. It is often necessary to remove the diseased focus in the bone or to resect the head of the humerus. But it should not be forgotten that even purulent joint infections may heal without operation and even leave a movable joint.

#### ELBOW.

Primary synovitis in the elbow is rare, the disease usually starting in the olecranon or in one of the condyles. The usual course is slow. Small bone foci remain localized for some time without giving symptoms. The diagnosis can often not be made until perforation into the joint has taken place. Such a perforation often follows a slight trauma, and the trauma is thus looked upon as a causative factor of the disease. The x ray will find small bone areas, and is, therefore, a valuable aid to early diagnosis. When the joint becomes affected there is an exudate formed which distends the capsule. To this is soon added periarticular edema, the muscles of the arm and forearm atrophy, and we have, then, the characteristic spindle shape. After the synovial membrane becomes affected, motion of the joints is painful. In the majority of cases abscess followed by fistulae result. The ligaments may become so destroyed that abnormal mobility results. Many cases do not come for treatment until late in the disease, owing to the very gradual onset. Naturally the prognosis varies with the extent of the disease. In early cases it is very good.

*Treatment*.—Owing to its accessibility, the injection treatment of iodoform is of great value. The

Bier treatment is also useful. If a fistula is present, the iodoform can be injected directly into it. Sometimes there will be marked improvement for several weeks, and then no further progress can be made by this treatment. An x ray picture will show a small bone focus, which, after scraping out, will be followed by a rapid cure. Especially in children should we be ultraconservative, and we will often be rewarded by surprisingly good results. But we must individualize, not work by rule, and, above all, watch our cases very carefully during the whole course of treatment. Often when we are in doubt, the x ray will point out to us the next step in the treatment. Advanced cases with multiple fistulæ and much destruction of joint will, especially in adults, require resection of the joint.

#### WRIST.

We must distinguish between a lesion in the joint and a lesion in the tendon sheaths. The disease can extend from the tendon to the joint. It is rare in children, commoner in adults, but usually associated with other tubercular processes, especially of the lungs. There may be a serous exudate, a dry necrosis of bone, or general involvement of the entire joint. There is frequently a history of injury preceding the symptoms. The disease often starts in the radius or metacarpal bones, although much oftener in the carpal bones. Frequently the disease starts in the synovial membrane. There is swelling, disability, and atrophy of the forearm. We seldom find much bone pain unless the process remains localized to one focus. Here again we find the spindle shaped swelling. There is doughy œdema of the skin, increasing disability of the fingers, and fistulæ often develop. Owing to the ease with which x ray pictures can be taken, they are a valuable aid, not only in making the diagnosis, but also in locating the various foci.

*Treatment.*—In children, again, we should be very conservative. In adults, especially if other lesions are present, the treatment should be operative. The details of the conservative treatment are similar to those referred to in tuberculosis of the elbow.

46 EAST SEVENTY-EIGHTH STREET.

### GASTROENTEROSTOMY IN CANCER OF THE STOMACH.

*With Report of Two Cases; Also a Third Interesting Case Diagnosed by Examination of Shreds of Tissue which Came Away During the Use of the Stomach Tube.\**

By JOHN J. GILBRIDE, A. B., M. D.,  
Philadelphia,

Professor of Diseases of the Stomach and Intestines, Philadelphia Polyclinic; Assistant Demonstrator of Anatomy at the Medico-Chirurgical College.

Charles Kingsley in his book *Westward Ho* says of the elder Leigh of Burrough that he was one of those men, moreover, who possessed almost every gift except the gift of the power to use them.

Might not this be applied to the position of many of us in reference to cancer of the stomach. The signs, symptoms, and laboratory methods for diag-

nosing this disease early, while of value, are unsatisfactory, and of no value whatever, unless the possessor of this knowledge applies it. Too often in the early stages of the disease no effort is made to use these means of diagnosis; the result is that the disease has already passed into an advanced stage before being recognized, and either no operation can be performed, or the palliative operation of gastroenterostomy is all that can be applied.

Gastroenterostomy was introduced into surgery of the stomach by Wölfler (Die Resection des carcinomatös erkrankten Magens; *Wiener medizinische Wochenschrift*, 1882, No. 14), who performed this operation in cancer of the pyloric end of the stomach, in which complete resection of the diseased pylorus was no longer possible.

Unfortunately, in nearly 80 per cent. of the cases of gastric cancer submitted to operation the disease is too far advanced to permit of a radical operation. Out of 313 cases of cancer of the stomach operated on up to February 1, 1906, by the Mayos (*Journal of the American Medical Association*, April 7, 1906, p. 1006) only 26 per cent. were early enough to permit of radical operation.

Widespread adhesions, metastases, and great loss of strength are contraindications against resection. Extensive adhesions between the growth and surrounding structures not only render radical operation more difficult of performance, but they also form channels along which the spread of the disease is apt to occur. The Mayos state that they have dissected into the superficial surface of the pancreas a number of times without that fatality to which Haberkant (76 per cent.) and Mikulicz (74 per cent.) have called attention. Moynihan reports a case in which the involved transverse colon was also removed, together with the stomach, with the patient living at the time of the report, two years after the operation. It is true that in the great majority of cases the growth will recur either locally or generally, but the advantages of gastrectomy as compared with gastroenterostomy are that it prolongs life about ten months longer, it affords a greater degree of comfort to the patient, and the patient has a chance of complete recovery. There are also a number of surgeons who advocate resection as a palliative operation, even in those cases where lymph glands are irremovable or an early secondary deposit in the liver has occurred.

The advances made in the surgical treatment of gastric cancer have gone beyond all expectations, as the mortality following both radical and palliative operations has been a gradual but continuously diminishing one, so that at the present time, according to the Mayos, the mortality is not over 10 per cent., and in selected cases the death rate is as low as 5 per cent. Of course, cases operated on in the late stages of the disease will continue to show a high percentage of mortality. Again, it must be remembered that all the cases treated medically die. Mayo also reports 25 per cent. of the operative recoveries, after resection, as living for more than three years. Other cases are reported as living a longer time, some of which are believed to be cured: One living five years, the Mayos; one living eight years, and one living thirteen years, Kocher; a woman living and well nearly six years, and a man living and well

\*Read before the Philadelphia County Medical Society, January 22, 1906.

nearly ten years after resection, Berg. (*Hygiea*, Stockholm, No. 307, through the *Journal of the American Medical Association*, December 14, 1907, page 2048.) While the radical operation is the one of choice, if, after opening the abdomen, it is found that resection cannot be applied, and that stenosis of the pylorus, or stagnation of the stomach contents, be present, a gastroenterostomy should be performed. There is usually a stenosis of the pylorus, as about 80 per cent. of gastric cancers occur at the pylorus and lesser curvature.

In cancer involving the curvatures without stagnation of contents nothing is accomplished by doing a gastroenterostomy. However, with the perfection that has been attained in the technique of these operations it is not unreasonable to expect that a greater number of cases of cancer of the stomach will be subjected to early operation at a time when complete removal of the growth and involved lymphatics may be accomplished. There is no doubt about the advisability of performing a gastroenterostomy if indicated, because it may be possible in some cases to do a radical operation when nothing more than a palliative one was intended. There is generally considerable improvement in the health and well being of the patient after gastroenterostomy. Vomiting ceases, the appetite returns, and the weight remains stationary or improves for a time. The stomach is more quickly emptied and there is a lessening of the irritation caused by the food passing over the surface of the growth. Katzenstein (*Deutsche medizinische Wochenschrift*, xxxiii, No. 4, through the *Journal of the American Medical Association*, March 16, 1907) is of the opinion that the pancreatic juice passing over the surface of the cancer after gastroenterostomy checks the growth, the surface of which it presumably digests.

The prolongation of life after gastroenterostomy is usually from three to six months, and after resection is on an average of fourteen months.

Now that surgery has definitely shown that it has something to offer sufferers from cancer, the next thing is to create a favorable public opinion by letting it be known that cancer has been cured and can be cured by early operation. The education of the people on this point would, to my mind, give a most wholesome impetus to the proper treatment of this disease.

The delay in bringing these cases to the operating table is not only due to our unsatisfactory means of diagnosis, but to the lack of enthusiasm among many members of the profession, as well as among the laity. An early diagnosis is difficult, sometimes impossible; however, if the methods of diagnosis which we now have were more generally applied many more cases should be recognized at a time when radical operation might be performed. These methods are neglected, except by a comparatively few; even the simpler forms of physical examination, and the notwithstanding the pleading of the best men of the profession for early diagnosis and early operation. He who has made an examination of his patient and tried to make a diagnosis is doing his duty, but he who has kept a patient under treatment and made no effort to diagnose the case until the patient says he has "black vomit and a tumor" is per-

forming the function of a patent medicine. "Coffee ground vomit" and a tumor are frequently only ante-mortem signs.

Until recently the onset of gastric cancer had been considered to be usually of one type, that is, it occurred most frequently in individuals past forty who had been previously free from dyspepsia, and that if the symptoms had persisted for more than eighteen months or two years the disease was probably not cancer. However, we now recognize two other distinct types of onset; one, where the cancer develops on an ulcer that may have caused symptoms at either a recent or a remote date preceding the cancerous invasion, and it was formerly believed that this change occurred in only from six to ten per cent. of cases, whereas we now know the change happens in a much greater number of instances. According to the Mayos (*Journal of the American Medical Association*, April 2, 1906), 56.4 per cent. of their last thirty-nine cases of cancer of the stomach operated on showed direct evidence of carcinoma developing on an ulcer. Moynihan (*British Medical Journal*, February 17, 1906) gives 72.1 per cent., and some writers even a higher percentage of cancer developing on an ulcer. This knowledge has been gained from operations performed for gastric ulcer, its complications, etc., and could not have been obtained from post mortem examination. The other and third type of onset is in cases that give a history of dyspepsia extending over a period of from two to fifteen years, and, in some few instances, even a longer time. The presence of lactic acid in the stomach contents is a valuable sign in diagnosing this disease; however, it should be thoroughly understood that lactic acid is usually, I believe it is always, absent in the early stages of gastric cancer, and one should not, therefore, wait until lactic acid is present to diagnose cancer.

The presence of a tumor, if small and movable, is not a contraindication to radical operation, for the reason that the majority of tumors occur at the pylorus in the most accessible part of the stomach to examination, and the fact that there are usually symptoms of stenosis which direct the attention of the patient more forcibly to the disease and lead him to seek medical advice earlier than he otherwise would.

In the performance of gastroenterostomy in gastric carcinoma the posterior no loop method with a double row of sutures is the method of choice, with the jejunum continuing its normal course to the left. When adhesions are too extensive and do not permit the performance of the posterior operation, the anterior anastomosis should be performed, the jejunum being raised in front of the transverse colon, and the anastomotic opening in the jejunum made at a distance of from ten to fourteen inches from its commencement, sufficient distance being allowed, so that the transverse colon will not be obstructed. In the employment of either method the anastomotic opening in the stomach should be made at a point far enough away from the diseased area to avoid the probability of an early involvement of the esophagus by the extending disease, with a return of symptoms of obstruction. If the anterior operation is applied this should be followed by the performance of an

enteroenterostomy between the afferent and efferent loops of intestine comprising the anastomosis. The double row of suture method is here, too, preferable.

The cases that I have to report are the following:

CASE I.—J. V., male; white; age sixty-five years; born in the United States; bricklayer; consulted me June 28, 1906, six months after the onset of symptoms. (See Fig. 1.)

Family history: Father died of consumption of the bowels at sixty-two years of age.

Previous history: While in the army during the civil war he had suffered from intermittent attacks of diarrhoea.

FIG. 1.—Cancer of the pylorus (CASE I).

He also had had inflammatory rheumatism at that time, and had had influenza in 1891. Otherwise he was perfectly well and in good health up to Christmas time, 1905, when he began to have a dull pain in the epigastrium after eating, lasting about two hours. The pain would then disappear to return after the next meal. There was also some fullness and distress after meals. He has been gradually getting worse. Vomiting began in May, 1906, occurring about once a week and consisted of probably a quart of a black, tarry material. His appetite began to fail about six weeks before consulting me, and food had no taste recently. He belched considerably, and the bowels were constipated. He felt very weak and tired easily. Weight at the time of onset of symptoms was 205 pounds; at the time of my examination he weighed 155 pounds—a loss of 50 pounds. Sleep was restless; no cough or headache.

Physical examination: Patient was a large, strongly built man; there was some wasting, but no cachexia. Color was good; mucous membrane slightly pale; examination of eyes was negative; teeth showed to be defective; tongue was slightly coated; there was no pulsation in the neck or palpable lymphatic glands. Chest was emphysematous; lungs and heart examination proved negative; radial pulses were equal; arteries were atheromatous. Liver dullness began at the sixth rib; lower border not palpable. Inspection of abdomen: Abdominal wall flat and relaxed with slight distention and a globular swelling in the epigastrium to the left of the median line extending under the left costal border, and corresponding in size, shape, and position to a distended stomach, the greater curvature of which was not below the normal position. Peristaltic waves were passing slowly and at regular intervals from left to right. An oblique inguinal hernia of the right side was also present. Palpation of the epigastrium showed an increased fullness

and resistance, but did not at first reveal the presence of a definite mass. However, the peristaltic waves indicated conclusively the presence of stenosis of the pylorus, and by laying my hand almost flat upon his abdomen, with a little deeper pressure exerted by the tips of the fingers over the epigastrium up beneath the liver, and gently stroking the abdomen downward during deep inspiration, holding the parts during expiration, I was able to bring down below the liver a tumor of the pylorus which was about nine centimetres in its transverse diameter by six centimetres vertically. It was hard and nodular. The finger tips could be placed between the growth and the liver, to which it seemed to be strongly united, as the mass could not be held down during expiration. This I attributed to a densely involved gastrohepatic omentum and to the fact that the growth was also adherent posteriorly, both of which conditions allowed but a slight mobility of the growth, and the operation which followed a few days later showed this supposition to be correct. The epigastrium was only slightly tender, and the growth could be handled without causing pain or discomfort, except a little nausea. Gastric tympany began at the sixth rib in the left nipple line and the greater curvature extended two and a half inches below the left costal border. Gas could be heard escaping through the pylorus. Kidneys or spleen were not palpable. Webster's and Stillé's signs were absent. Left supraclavicular lymph glands were not palpable. Physical examination was otherwise negative. Urine examination was negative. Analysis of gastric contents after an Ewald test breakfast: Aspirated 100 c.c. of a black "coffee ground material"; contents fairly well digested; slight amount of mucus present; reaction to Congo negative; total acidity 0.30; free hydrochloric acid absent. Lactic acid test showed a positive reaction. Blood positive. Microscopical examination of the gastric contents was not made. Occult blood also in the faeces, using the alouin test.

The diagnosis of gastric cancer was made, and an operation was advised which I performed at St. Joseph's Hospital on July 5, 1906. On opening the abdomen the stomach presented showing the growth as described and involving the whole pyloric end of the stomach, also extending more along the lesser curvature. The gastrohepatic and gastrophrenic ligaments were thickened and the lymph glands enlarged; one lymph gland overlying the cardia was the size of the distal phalanx of an adult's thumb. Adhesions were so extensive posteriorly as to render it impracticable to do a posterior gastroenterostomy, therefore, an anterior one was performed without doing an enteroanastomosis. The abdomen was closed in the usual manner, and the patient recovered from the operation without a bad symptom. He was up in a chair at the end of five days and had his clothes on, and out upon the floor at the end of eight days, leaving the hospital in three weeks. His appetite was excellent and he relished his food; he resumed light work during September and October, and died November 26, 1906. No autopsy.

This man had been under treatment for dyspepsia from the time of onset of symptoms and he said he had not been examined even in so far as to show his tongue. The man was an admirable patient and anxious for anything which might save his life, but alas, too late!

CASE II.—(See Fig. 2.) L. S., female, age forty-seven, housewife, born in the United States, was seen in consultation with Dr. James L. Hornbeck, of Catauqua, Pa.

Family history: Father, seventy; mother, sixty-eight; both living and well.

Previous history: Married twenty-five years; eight children living and well. Patient had had measles when a child; malaria eighteen years ago.

Present condition began fourteen years ago by vomiting off and on at variable intervals of from once a day to once in two weeks or once in two months; no blood was vomited; there was belching, regurgitation of sour liquid at times. She had been gradually getting worse. Four years ago she had a rather severe attack of stomach disturbance which lasted between three and four weeks, confining her to bed. She had had similar attacks about once a year since the one mentioned. She vomited blood during an attack that occurred about a year ago. Constipation had pain during attacks only. The present and last spell began March 11, 1907, by loss of appetite, fullness, and distress after eating, vomiting every few days, the quantity depending upon the interval between each vomiting spell; bowels constipation alternating with diarrhoea; complained

of thirst and weakness; was gradually getting worse. She alternated with diarrhoea. Appetite was usually good in the intervals between attacks. Patient slept soundly and had been confined to bed from the middle of June until the first week of July, 1907; was then up and about for two weeks when she again took to her bed, where she had been for five weeks when I saw her, August 22, 1907.

FIG. 2.—Cancer of the stomach, gastroptosis, with dilatation. (Case II.)

**Physical Examination:** A large boned woman who was very much emaciated. The skin was dry, brownish, and shriveled. Tongue was dry, red, and slightly coated, showing that she was suffering from a toxæmia; lips were dry; teeth defective. Supraclavicular lymph glands were not palpable. Examination of lungs was negative; pulse was small, hard, and accelerated. Myocarditis and arteriosclerosis were present. Inspection of abdomen showed considerable prominence in the umbilical region and scaphoid above and below. This bulging was the dislocated and dilated stomach, the greater curvature being midway between the umbilicus and symphysis pubis, and the lesser curvature was midway between the xiphoid cartilage and umbilicus. Peristaltic waves were passing from left to right; succussion splash was present over stomach. There was a diffuse thickening of the stomach wall at the pyloric end. Gas could be heard passing through the pylorus at delayed intervals of from 30 to 40 seconds. The normal tone of peristaltic sounds at the pylorus was, according to Cannon, at intervals of about nineteen seconds, which observation I have also noted. The pylorus could also be felt to alternately contract and relax under the palpating fingers. Examination of liver, kidneys, spleen, etc., were negative. There was but slight tenderness over the stomach on palpation. A right femoral hernia was present. The woman was almost a skeleton, the muscles, as well as the paracostals having wasted away. Apiration of the stomach contents. It was not aspirated in truth, as the contents were so thick as to obstruct the tube and the patient vomited about two quarts of a thick, brownish, fairly well digested material of a sour odor. This on examination showed a total acidity of 0.58, free hydrochloric acid to Congo negative; free and lactic acid negative. Blood present, some mucus.

Diagnosis: tumor of pylorus; body's malnutrition; gastroptosis with dilatation; arteriosclerosis and chronic interstitial nephritis.

Operation upon the stomach was advised, and that in the event of the pyloric tumor not being malignant she would be given a chance for recovery. Dr. Hornbeck had ex-

hausted all medical means, including belts, drugs, diet, etc., and to his credit be it said he had had the patient under observation only a few months. Operation was consented to and she came to Philadelphia on August 27, 1907. I operated upon her at St. Agnes Hospital the following day, doing a posterior gastroenterostomy, as pylorotomy was out of the question on account of the emaciation, weakness, etc. There was a diffuse thickening of the pyloric end of the stomach, almost complete stenosis of the pylorus, which was hard and indurated, the glands at the pylorus along both curvatures were large and hard. The patient recovered nicely from the operation, getting up in a chair at the end of five days. Nourishment was begun early and forced. She had a good appetite and relished her food. The urine went as low as ten ounces a day for two days following the operation, and never above twenty-four ounces during the four weeks she remained in the hospital, although treatment against this condition was begun before the operation and by filling the abdomen with saline solution before closing, this was followed with saline by the rectum (Murphy's method), diuretics, including sparteine sulphate in two grain doses hypodermatically as the occasion required.

She had no further trouble with the stomach following the operation and returned to her home four weeks later. Her bowels continued loose off and on as before. Appetite was good. She ate her food well, but never gained strength, nor did the kidneys increase their function. She died the latter part of October, 1907. Dr. Hornbeck wrote me after her death that following the operation she did not suffer at all from her stomach and complained only of weakness. The cancer in this case, I also believe, in all probability, followed a chronic ulcer which was the cause of her long continued dyspepsia.

I will cite one other case, because it illustrates three points: (1) Diagnosis of cancer by examination of a piece of tissue that came away in the wash

FIG. 3.—Cancer of the stomach, with dilatation and gastroptosis. (Case III.)

water while using the stomach tube; (2) absence of lactic acid; (3) a clear history of ulcer of the stomach dating back twenty-eight years. Lactic acid was also absent in the other case above reported.

**CASE III.**—(See Fig. 3.) A. B., female, white, age forty-five years; born in Germany; housewife; came from Connecticut. Seen in consultation with Dr. Edward J. Menger,

of Philadelphia, November 5, 1907. She had been married twenty-two years; had had five children and one miscarriage.

Family history: Mother died of cancer of the stomach at forty-five years of age. One brother died of tuberculosis of the lungs at the age of twenty-five years.

Previous history: Vomited blood at seventeen years of age, believed to have had gastric ulcer and was kept in bed about twenty weeks.

Present condition: Began four years ago by failing appetite, fulness and distress after eating, belching, vomiting at variable intervals of from once in two weeks to once a day or once in two days. The quantity of vomitus was about a quart when she vomited every day, and may have been a little more when the intervals between vomiting attacks were longer. Sometimes her appetite improved off and on for a few days at a time; she then ate a little more and this was again followed by vomiting; but she felt better when she ate least. Pain had been present in epigastrium more or less all the time for the past several years. It was relieved by vomiting or by lying down. No headache; bowels were regular; there was burning sensation occasionally in the epigastrium; regurgitation of some liquid at times. Patient had lost about thirty pounds in weight in the last year; sleeplessness and palpitation; no swelling of the feet.

Physical examination: A medium sized, fairly well built woman showing some wasting, but not cachectic or emaciated; teeth very defective and tongue coated; examination of lungs and heart were negative; supraclavicular lymph glands were not palpable.

Inspection: Abdominal wall was relaxed and there was a prominence about the width of a hand extending from beneath the left costal margin downward and to the right parasternal line. The centre of its vertical diameter was at the umbilicus. Below the xiphoid cartilage tenderness on palpation was quite marked. Splashing was present over the stomach, which was dislocated downward; no peristaltic waves were visible, nor was there any mass palpable, the right kidney and stomach, of course, being excepted. The right kidney occupied the third position of dislocation, as the tips of the fingers could be placed above the upper pole of that organ. Liver, left kidney, or spleen, were not palpable. Webster's and Stiller's signs were not present, no tenderness along the left side of the spine posteriorly (Boas sign of gastric ulcer). Examination of gastric contents following an Ewald test breakfast: Time forty-five minutes; aspirated 20 c.c. of fairly well digested contents; some blood streaked mucus, and a few drops of bloody liquid dangled from the end of the tube on withdrawal. Total acidity 0.50. Free hydrochloric acid to Congo positive; by analysis 0.10. Blood was macroscopically present. On examining the wash water I noticed a few small pieces of supposed mucus which resembled mucous membrane and which I had examined by Dr. Wieder at the Medico-chirurgical College and by Professor Joseph McFarland, of the same institution. It was pronounced by them cancerous.

An operation was advised, but the woman, who had returned to her home in Connecticut, refused her consent to operation.

A patient who in middle or advanced life is suffering from dyspepsia should have the stomach contents examined, not once, but several times, if necessary. This can be readily carried out by giving an Ewald test breakfast on a fasting stomach; two small slices of bread and about a pint of water are given. Aspirate the stomach contents in forty-five minutes and examine. If the attendant is unable to examine the contents himself, he should shake it up, put some or all in a bottle, seal, and send it to some one for examination and report.

Suspicion of the presence of malignant disease of the stomach calls for an exploratory laparotomy. Contraindications to any operation on the stomach are involvement of the supraclavicular lymph glands, particularly those on the left side, other extensive involvement, advanced cachexia, and

One hears the statements made on every side, by the uninformed, of course: "We have nothing that will cure those cases, and what can we do until we know the ætiology?" These are but lame excuses for inactivity.

Let those who offer these statements arouse from their lethargy, and when a diagnosis has not been made until the life of a dear one is ready to pass over the river beyond, not console themselves with the thought that the disease was incurable anyway. Why sit idly by when men like Billroth, Krönlein, Mikulicz, Robson, Moynihan, Deaver, the Mayos, and others have carried or are carrying the light and showing us that some of the cases subjected to early radical operation are cured? We have a remedy, the only one at present—surgery. Apply it promptly and judiciously, and when the last shades of the twilight of life will have fallen around the chamber of those afflicted with this disease, let us be able to feel and say, even though we fail at times, but not always, that we have done our duty, we did our best to save our patients from death by this disease.

#### CHRONIC ALCOHOLISM:

*What Can and What Cannot Be Accomplished by Treatment.*

BY GEORGE E. PETTEY, M. D.,  
Memphis, Tenn.,

Member, American Association for the Study of Inebriety, etc.

The question is frequently asked: "What can be done by treatment for those who are enslaved by alcoholic liquors—can they be cured?" To this question both an affirmative and a negative answer can be made, and each would be correct when referring to a certain class of cases. Chronic alcoholism is not only a disease itself, but in many instances it springs from other diseases. These diseases may be either physical, mental, or moral. To cure any disease the cause must be removed. In some cases of alcoholism this can be done by treatment, while in others it cannot; then the question naturally arises, what class is curable and what is not? In endeavoring to answer this question it is necessary to consider the type of the addiction as well as the influence which led to its formation. In doing this it is well to first divide the drinkers into two classes, the regular drinkers and the periodical drinkers, then to study very carefully the influences and causes that led to the formation of the addiction. It will be found in many instances that these differ materially in the case of the regular drinker from those of the periodical drinker.

#### *Regular Drinkers.*

Probably 80 per cent. of all persons who drink whiskey regularly, day by day and week by week, got into the habit inadvertently, unintentionally. They were persons of sound bodies and minds, good habits and high aims, who began to use liquors in a social way, or probably with the idea that their effects would protect them from malaria or other prevalent disease. They continued this course without mature thought as to its consequences and certainly without any purpose to go to excess or

dissipate in any way. The use of a stimulant gradually grew more frequent, finally leading to the daily consumption of considerable quantities of some alcoholic beverage. For a time the effects of this beverage seemed to improve the health, to impart greater mental and physical vigor, and to generally promote the well being of the subject, but these benefits were more apparent than real, and all this time there was being created in the system a demand for the effects of alcohol, and this progressed until the user felt more comfortable when under the influence of the stimulant than when not. Thus, gradually, and almost imperceptibly, the demand for the stimulant grew, and the victim became more and more dependent upon it, until larger and larger quantities were required to meet this demand. The daily consumption of these considerable quantities of liquor necessarily brought on such changes in the system as to create an imperative demand for the continuation of their effects. After reaching this stage the victim felt that he could not begin his day's work without his morning drink; there was a degree of lassitude and lack of vigor that he was totally unable to throw off except by the aid of a stimulant. As these disorders progressed, one drink was not sufficient to give him the necessary support, and two, three, or more were taken in close succession, and this bracing process was continued throughout the day and from day to day and from week to week. The effects of this prolonged and free use of alcohol wrought serious impairment of the digestive organs; the appetite became variable or absent altogether unless freshly stimulated by an extra drink, and if, at this or any subsequent stage the victim made an effort to discontinue drinking, such a state of nervousness would result as to drive him to resume the stimulant. The entire system had by this time become so thoroughly saturated with toxic matter, of such an extremely irritating kind, that a condition of intolerable nervousness would arise whenever the system was allowed to get out from under the *novu sedative* influence of liquor, and no matter how acutely conscious the victim may become to his slavery or how heroically he struggles to throw off the yoke he finds himself unable to do so by his own efforts. The prolonged free use of alcoholic stimulants brings about such disorders of the system as to lead even the best of men, when in its grasp, to continue to seek relief from the suffering incident to these disorders by increasing the quantity of alcohol consumed. Whether that course is imperatively necessary or not, it appeals to them as being the one readily available and efficient remedy, the panacea for every ill, and it is so used.

A majority of all habitual users of alcohol in this country belong to this class, and many of them would gladly quit drinking if they could ever get the poison out of their systems, and reach a condition in which they could live in comfort without it, but they seem never to be able to do this. They never get entirely sober, and their systems are never clear from the products of tissue waste. They are always in an extremely toxic condition, and are only comfortable when the paralyzing effects of alcohol blunt their sensitivities to the presence of this poison. In habitues of this class, the

addiction has a purely physical basis, due to the effects of alcohol alone, a combined chronic auto-toxæmia, and drug toxæmia, and as both of these elements are susceptible of being removed by treatment, cases of this class are curable.

In the second division I would place a small per cent. of regular drinkers who were born with, or who from disease in early life acquired, a defective physique and an unbalanced nervous system, persons who, because of such defects, have never been normal either in nervous or physical organization. When such persons, in seeking something to overcome their habitual discomfort, experience the effects of alcohol they readily fall a victim to its seductive influences. For a time this stimulant seems to be the one thing lacking in their lives; it overcomes that discordant nervous condition which they so much dread, and they feel that they have found a panacea for all their ills, but this relief is only temporary. The demand for the effects of alcohol grows very rapidly in such cases, and its continuous use brings on the same pathological conditions that it does in others. The system soon becomes extremely toxic, and this irritating matter greatly aggravates their former nervousness, so that the two conditions together now make such an imperative demand for liquor that the victim cannot in any wise resist it, and he keeps himself constantly satiated with alcohol—in fact, after reaching this stage he must do so to enjoy the least degree of comfort. In this class of cases but little can be expected from treatment, unless it is found that the original discordant nervous element can also be removed by treatment. When these causative conditions are found to be such as to be amenable to treatment, and the treatment for the addiction embraces not only such treatment as would be necessary to give relief in an ordinary case, but also such other well directed measures as may be required to restore the primarily unbalanced nervous system to a normal condition, much benefit may be derived from treatment even in these unpromising cases, provided a reasonable degree of moral fibre was originally present.

In a third division I would place another, but relatively small, proportion of regular drinkers. To this class belong those who drink as a pure dissipation, persons who are deficient in moral fibre, lacking in purpose, supremely selfish, willing to gratify the present moment at any cost to themselves or others, without a normal sense of responsibility: those who are simply drifting through the world without *oultury*, compass, or objective point. These defective traits of character may be due either to inherited tendencies or to early environment. Such persons as these drink because they prefer to do so, and would return to the use of liquor even if some one took them up and gave their systems a thorough renovating and removed all physical necessity for the stimulant. In cases of this class more than human agency would be necessary to effect a cure. Not only would it be necessary to regenerate their bodies and put them in normal condition, but it would be necessary to effect a most radical change in their moral natures, a complete transformation of their purposes, beliefs, and nothing short of the grace of God is sufficient

for such a work. Human agency will not avail. Fortunately only a small proportion of the regular drinkers belong to this class; the great majority are of the class first described in this paper. They are men or boys of good families, of excellent traits of character, of high aims, chivalrous, generous to a fault, truthful, and honest—in fact, men with whom no fault can be found except this one weakness, and that due to the lamentable fact that they have drifted into the clutches of this monster. Victims of this class only continue to drink because their willpower and selfcontrol have been so undermined by the effects of alcohol that they cannot extricate themselves from its clutches; they cannot retrace their steps. When such men as these are once freed from the domination of alcohol and are put in a normal condition they will maintain themselves and almost invariably remain permanently free from its thralldom.

Failure to permanently benefit such men as are described in the second and third division should not be allowed to discourage us or to make us less enthusiastic in our efforts to rescue the more numerous and really noble army of enslaved ones.

#### *Periodical Drinkers.*

These should be divided into four classes, and probably some of these classes should be still further subdivided in order to get a clear conception of each class. There are at least four sets of causes that lead to periodical drinking among men who are entirely sober between such sprees. These should be enumerated as: Dipsomania, real and symptomatic; moral cowardice; environment with lack of stability of character; environment with an ever present but resisted appetite.

*Dipsomania.*—Dipsomania is defined to be “an uncontrollable desire for strong drink,” but this term should be restricted to those cases in which this desire or impulse springs from a real mental disorder, a true mania, and should not be applied to those cases where the desire for drink only becomes uncontrollable when it is excited or intensified by some general physical derangement, or where the desire is continuous. A better definition would be “periodical insanity taking the form of an uncontrollable desire for strong drink.” Real dipsomania is very rare, but that it does exist cannot be denied. Most writers leave the impression that such attacks are due entirely to some obscure structural brain lesion or inherited mental defect. It is doubtless true that there are persons in whom a real mania of this type occurs because of an inherited mental bias, or perverted nervous organization independently of the general physical condition, but, in my judgment, such cases are extremely rare. In a large majority of cases which are thus classified the attack only occurs when excited by an added general systemic derangement, an acute autotoxæmia. The irritating effects of this toxic matter serves as the exciting cause of the outbreak, and in most instances these attacks may be warded off or prevented altogether by keeping the system free from toxic matter. Where outbreaks of this kind occur as the result of an inherited or acquired mental defect, entirely independent of the physical condition, treatment cannot be expected to be of permanent benefit, but in cases in which such at-

tacks only occur when an exciting cause, such as autotoxæmia, contributes its influence, then treatment will be of real benefit, provided it embraces such instruction in the manner of living as to enable the victim to avoid the occurrence of such toxic states.

*Moral cowardice.*—Another and probably the most hopeless class of periodical drinkers are those who drink as an expression of moral cowardice. These are men who have no particular craving or appetite for liquor, and who will say at almost any time that they do not particularly care for the taste or primary effects of alcoholic drinks, but who have learned from experience that the effects of alcohol will bring them surcease of cares and worries which they have not the moral courage to take up and bear, and from time to time they seek forgetfulness in the effects of liquor. A man of this class will quarrel with a friend or his wife and go off and get drunk for spite, or he may have some business experience which to other men would be trivial, but he, not having the moral courage to face it, runs from it and seeks oblivion in the effects of alcohol. Little if any good can come from treatment of patients of this class. Therapeutic measures cannot remove these incumbrances from their lives, or impart to them that degree of moral courage that is needed to fit them to fight the battles of life in the open and to resist the adverse current which drifts them from a safe and sober mooring.

*Instability of character with bad environment.*—In another class of periodical drinkers the sprees are due to “bad environment coupled with lack of stability of character.” These are the social drinkers of the type who lose control of themselves as soon as one drink is taken. Many of these are men of estimable qualities, amiable, chivalrous, good hearted, kind, and in every way lovable men, but they are deficient in selfcontrol, fixed purposes, and positive traits of character. They are good natured fellows who drift with the current and allow others to dictate their course. These men, when away from the drinking associates and out of temptation, remain entirely sober, and would not think of going alone and deliberately beginning to drink; they have no craving or appetite for liquor that they are not fully able to control, but they are negative characters, and when thrown with drinking associates they do as others do. They are of the type of social drinkers who lose control as soon as they are slightly under the influence of alcohol. When once started, such men continue to drink until some one takes control of them and gets them out of the adverse current. Then a period of entire sobriety follows, only to end in another spree when they get into the current which drifts in that direction.

Treatment in such cases can only be successful when followed by an entire change of environment. The old associates must not only be given up, but the one seeking to reform his life must be thrown with sober and moral people whose positive influence for good over him will be sufficiently strong to enable him to stand firmly in his new position, notwithstanding his defective traits of character.

*Bad environment with an ever present but re-*

*sisted appetite.*—Another type of periodical drinkers are those who have an inherited or acquired thirst or craving for liquor which is ever present with them, but who, from strong convictions, contend against this weakness with a courage that is in many cases really heroic, and, under favorable circumstances, they succeed in controlling themselves, but when thrown with drinking associates or when brought under other strong temptation then they find themselves unable to resist both the ever present thirst and the temptation. Under these circumstances they begin to drink, and as soon as one drink is taken their resisting power is gone, and they throw themselves into the spree with a vigor and abandon that is not known to the more timid or less resolute. They continue to drink until the stomach rebels and will no longer retain the liquor; then they go through a period of extreme distress and remorse, and finally get back on their feet.

Periodical drinkers of this type are more amenable to treatment than any other form of periodical drinkers, because the craving, the thirst against which they contend, can be overcome—in fact, entirely destroyed. In addition to this their attitude toward liquor can be so changed as to render the taste small, and the effects of liquor repulsive to them. When men of this type are given this much aid they find themselves quite able to successfully contend against the influence of drinking associates and to resist other currents of influence which, when associated with their former craving, would have been sufficient to cause them to fall.

#### *Principles of Treatment.*

Before undertaking to treat any disease we should endeavor to ascertain the nature of the condition to be met: whether such a condition has a real, structural pathology or is only functional derangement, and whether it is a physical or a mental disorder. That the prolonged use of alcoholic stimulants does cause serious structural lesions of the brain, liver, stomach, and other organs cannot be denied, but such lesions are not the only or principal reason for the continuation of the habit. In some cases, as we have seen in the preceding, the use of liquors are continued from preference, or because of some mental or moral defect, but in the great majority of cases alcoholic drinks are continued because of a strong demand in the system for their effects. *The habit has a real physical basis.* This demand for the effects of alcohol is due to the extremely toxic condition of the system. Alcohol blunts the sensibilities of the nervous system and retards the excretion of the products of waste. The life of the human organism is a continuous process of waste and repair. When the excretion of this waste is retarded, even to a slight degree, day by day, the system finally becomes so saturated with poisonous matter as to cause serious functional derangement of almost every organ in the body. One in this condition finds it necessary to keep the nervous system constantly blunted with the effects of alcohol or other narcotic to enable it to carry on the work necessary to support life and promote a reasonable degree of comfort. While it is true that alcohol has caused these disorders, still its effects relieve the acute distress springing

from them more promptly and in a manner more acceptable to the sufferer than anything else with which he is familiar, therefore he continues to seek what comfort he can get by taking more alcohol, and thereby burns the taper at both ends.

In endeavoring to bring about such a change in this condition as to render the further use of alcohol unnecessary, the first and most important step is to thoroughly cleanse the system from the products of waste which the effects of alcohol have forced it to retain. In doing this the bowels, kidneys, and skin should all be made to do their full share—in fact, for a time these should be made to do many times their ordinary duty. Just in proportion as the excess of toxic matter is eliminated will the nervous system become quiet and the urgent demand for the effects of alcohol disappear. As a rule, in the course of three or four days the system may be so cleansed of toxic matter as to permit the withdrawal of alcohol without risk or discomfort to the patient. I do not consider it safe or at all advisable to abruptly withdraw alcoholic stimulants from one who has been using them in large quantities without first preparing the system for such withdrawal. After the system is properly prepared for the withdrawal it may be made with perfect safety and without discomfort, but I cannot agree with the arbitrary rule of cutting off the alcohol as soon as the patient is taken in hand.

Up to this point the treatment of the several classes of alcoholic cases is practically the same, as all of them require elimination of the toxic matter and the withdrawal of alcohol, but from this point on the several classes of cases will require radically different lines of treatment. The particular nature of the treatment required to complete the cure will depend upon the cause, or set of causes, which originally led to the formation of the habit, as well as those which have had an influence in its continuation. If these were purely mental, then treatment calculated to overcome a mental disorder should be given; if they were moral or social, then those influences should be looked into and every effort made to direct the patient's future life so as to protect him from these damaging influences and prevent a return to his old haunts and habits.

If the patient belongs to the more promising class, the regular drinkers, in which the habit was continued because of the usual mental bias favorable to the use of alcohol, and because of the deranged physical condition resulting from its effects, then the succeeding step in the treatment should be to neutralize the remnant of alcohol remaining in the blood, to overcome any appetite which may remain for it, and to supplant the mental bias favorable to alcohol with a dislike or complete disgust both for its taste and effect. The means available for these purposes are so numerous and their application so varied that they do not admit of detailed discussion in an article of this kind. In addition to the well known therapeutic agents, static and other forms of electricity, vapor, shower, or neutral or electric baths, suggestion, and in some cases even hypnotic suggestion, dieting and physical training may be used to advantage.

While these corrective measures are being con-

ployed active therapeutic measures calculated to overcome the catarrhal condition of the stomach should also be employed. This condition is the remaining disorder which would exert the greatest influence toward a return to the old habit, because of its effect in impairing digestion.

Fortunately catarrh of the stomach yields readily to treatment in these cases after alcohol has been discontinued, but active treatment for this disorder is essential, and it should be continued until all trace of it has disappeared and the patient's digestion is perfect. He should be able to eat and enjoy three good meals a day. Patients of this class need the strength derived from the digestion of a hearty breakfast in order to prevent them from feeling the need of the support they formerly received from alcoholic stimulants. No part of the treatment is of greater importance than this, since, if it is not successfully carried out, the patient will not be as secure from relapse as he should be. Impaired digestion, with its attendant lack of strength, operates as an ever present influence suggesting the need of some stimulant, some outside supportive, and this amounts to an autosuggestion to take a drink. This is a dangerous condition for the patient to be left in.

The conditions to be met in a majority of cases of alcoholism are simple, and the treatment can be easily carried out, while in others they are so complicated that the resources of the best equipped institution as well as the skill of the most resourceful physician will be taxed to the uttermost; but with the aid afforded by a well equipped institution a competent physician can effect as large a percentage of permanent cures in cases of chronic alcoholism as can be effected in any other serious ailment. The most skilful physician cannot treat them successfully at their homes. The disadvantage due to their home surroundings and to lack of perfect control of his patient will defeat his best efforts. Even a general hospital does not assure the physician such control and protection as this class of patients require.

I do not feel that I should close this paper without a warning against any institution or physician offering to send a home treatment for alcohol or drug cases. Such an undertaking is worse than folly, and when a proposition of that kind does not spring from entire ignorance of the conditions to be met, it is prompted by criminal avarice. Especially fraudulent is the offer to send a remedy that can be administered in coffee, etc., without the patient's knowledge, and thus overcome the desire for liquor and break up the habit.

In undertaking the treatment of alcoholic cases the physician should take a comprehensive view of the patient and his surroundings, and endeavor to correctly estimate every influence which has in any way contributed to his enslavement, and to so manage the treatment of the case, and to so direct the life of the patient thereafter, as to remove every one of the hurtful influences as far as it is possible to do so. The physical man must be completely renovated, and every function of his body restored to normal activity. The mental bias favorable to the use of alcoholic liquors must be eradicated, and in its stead a positive aversion to alcohol be established. The patient is to be given a new chance in life by being put back on his feet with a clear head, in full

control of all his faculties, and free from the dominating influence of alcohol. The consummation of such a work is certainly worthy of the best efforts of any man.

958 SOUTH FOURTH STREET.

## CARIOUS TEETH IN THE TENEMENT POPULATION OF NEW YORK CITY.\*

BY HAVEN EMERSON, M. D.,  
New York.

From June to September, 1907, I had the opportunity of examining the teeth of 2,301 applicants for the Sea Breeze Health Home at Coney Island, under the auspices of the New York Association for Improving the Condition of the Poor. In each instance the mouth was examined in the usual manner with a tongue depressor, for evidences of contagious disease. The moment of this examination was used to note the number of teeth decayed as well as to count those lost, and the number replaced by artificial teeth. The data acquired in this manner are the basis of this report.

It is to be noted that none of these people, adults or children, were suffering from any acute diseases. The applicants were mothers and daughters over fifteen years, and children of both sexes from three weeks to fifteen years.

They had been invited to apply for a two weeks' stay at Sea Breeze, because they were known to need an outing, often owing to sickness during the previous winter, but in the majority of cases because their general health was failing, or they were giving evidence of lowered vitality, in various forms of malnutrition, anemia, and general debility. As they presented themselves for examination, they appeared rather above the poorest class of tenement dwellers. None had suffered from hunger, and all were sufficiently clothed.

The rapidity with which the examinations were made, and the lack on the part of the examiner of technical skill in observing dental defects, are responsible for at least a very conservative estimate. Only such cavities or distinct evidences of destructive decay in a tooth as were plainly visible on direct inspection were taken in the count as decayed teeth.

Of the 2,301 applicants examined, 189 were infants under one year, 1,478 were children from one to fifteen years, and 634 were women and girls over fifteen years.

Of the 1,478 children, 278, or 18.8 per cent., had no defective teeth, leaving 1,200, or 81.2 per cent. Among these 1,200 children I found 5,996 decayed teeth, almost five apiece, or an average of 4.7 decayed teeth for each one of the 1,478 examined.

Of the 634 applicants over fifteen years old, only 19, or 3 per cent., had no defective teeth, leaving 615, or 97 per cent., in whom 4,022 teeth were found to be decayed. This makes an average of 6.5 decayed teeth for each of the 634 examined. There were also found in this group 1,655 teeth missing, and, in addition, 1,444 artificial teeth, making a total of teeth which had been removed presumably for advanced caries of 3,099, or an average of 4.8

\*Read at a meeting of the Institute of Stomatology, on December 8, 1907.

for each one of the 634. Combining the numbers of those removed and those at present decayed, we have an average of 11.3 teeth decayed, or 28.8 per cent. of all the teeth of 634 adults severely enough diseased to be more or less permanently ineffective. It also appears that 7.2 per cent. of the entire number of teeth of these 634 adults were replaced by artificial teeth. Inquiry elicited the fact that only in the rarest instances were the toothbrush or even mouth rinsing used, and, as far as I could find out, no means of cleansing the mouth and teeth were considered to be worth while until the permanent teeth had appeared.

To those who are familiar with the conditions of patients who frequent the public medical dispensaries, these figures will probably seem moderate, and I do not doubt that an examination by a dentist would reveal a material increase in the number of carious teeth. These figures are, however, sufficiently striking to emphasize my point, that this defect in the teeth of the tenement dwellers must be corrected before we, as physicians, can remedy some of the serious evils of health and development which these people suffer from. I refer especially to the errors in digestion which originate in incomplete mastication and salivary digestion, with constipation as an almost universal accompaniment. The advanced results appear as malnutrition, underdevelopment, and lowered general resistance to infectious disease.

That mouth infections involving the fauces and tonsils are more common in individuals with many carious teeth, I have no figures to prove; but the condition of the soft tissues which come in contact with carious teeth, at the gum margin or upon the buccal or lingual mucous membranes, certainly suggests that there is a pretty constant source of septic or putrefactive bacteria in the crypts of the decayed teeth.

Wadsworth (*Journal of Infectious Diseases*, iii, No. 5, October, 1906) says: "From the hygienic standpoint, the secretions of the mouth constitute the chief, if not the only, source of respiratory infection, and the infectious material is transferred from one person to another in some instances through the air, as from sneezing or coughing, but to a much larger and more serious extent directly by personal contact, or the use in common of the various accessories of life."

I venture to suggest that one way in which the prevalence and increasing incidence of respiratory disease may be checked will be by a prevention and correction of dental diseases, supplemented by the use of bland alcoholic solutions as mouth washes, which Wadsworth found to be the only mouth disinfectants of practical value.

To summarize my ideas upon this subject I may say that carious teeth are so numerous among the tenement population of New York, and the manifest results of digestive disturbances caused thereby are so far reaching in their effect upon the welfare of the individual and the state, and the danger of communication of infectious disease is so much increased by the presence of unclean mouths, that prophylaxis and treatment of decayed teeth should be undertaken on a comprehensive scale as a public necessity.

The economics of public hygiene occasionally de-

mand considerable present burdens to avoid certain increasing difficulties and expenses in the future.

I believe the dentists of this city would be doing a work of great value to the public health, a work which they alone can do, and a work of immediate importance, if they would undertake the betterment of existing conditions in the present sufferers from decaying teeth, and so spread the knowledge of the needs and means of caring for the teeth that the children of the poor will not continue to grow up under a handicap, which, aside from the physical suffering often entailed, stunts their mental and bodily development and renders them alike disseminators of infection and fit subjects for infectious disease.

120 EAST SIXTY-SECOND STREET.

#### A PRACTICAL SYSTEM OF MEDICAL INSPECTION WITH TRAINED NURSES. ADAPTED FOR PUBLIC SCHOOLS OF LARGE CITIES.

By S. W. NEWMAYER, M. D.,  
Philadelphia.

After studying the various systems of medical inspection, with the aid of trained nurses, as employed in several large cities of the United States, and eliminating the useless and unpractical features, I devised the following system, which seems to give the best results. The chief factors to which I gave consideration were: 1. The elimination of useless clerical work. 2. Methods which would assure cooperation between medical inspector, nurse, principal and teacher, and parents. 3. The unnecessary exclusion of pupils, and, when excluded, their return in the shortest possible time. 4. Each party concerned assumes his or her share of the responsibilities, and errors can easily be traced to their source. 5. Records and reports are few and can readily be referred to for practical purposes.

Various bad features are noted in the systems employed in the different cities. One city is hampered by a law which admits of the doctor and nurse supervising only contagious diseases. This prevents them from recommending or treating some of the most important ailments of school children, such as defective vision or hearing, enlarged tonsils, and adenoids. Some cities have too few doctors and nurses to attend to the work, or the allotment of territory is poorly arranged. Consideration must be given to the distances between schools, and the kind of and not number of population in a district. A nurse or doctor can attend to more schools in a section of a city inhabited by the higher social classes than the doctor who attends to schools among the congested foreign element. In some schools the physician may see no more than a half dozen patients a month, whereas in the district of poorer people each school may send each day from twenty to fifty patients. School population is not a safe guide by which to allot the work. Sometimes a small annex with one hundred children takes as much time to inspect as a school of one thousand pupils.

Through a lack of understanding of the duties of the doctor and nurse, in some schools there is a waste of valuable time disposing of trifling worms, etc., when the same time could be used for most important examinations. Again, there is no necessity

of a teacher sending to the inspector the same child with the same ailment each day. The nurse should judge when she desires the doctor to again see the patient.

Instead of examining and re-examining normal children, every new child should receive a thorough physical examination on being enrolled, such as is performed in the schools of Philadelphia.

The blanks and system of keeping records seems to be the most difficult problem. Any system which requires writing a half dozen times the same name of school, patient, disease, recommendation, and treatment for each case is faulty. Aside from the enormous expense of printing large quantities of index cards and blanks which serve no purpose, one third of the time is wasted in recording and re-recording, with the result that it is difficult to again refer intelligently to the records. These facts should be written once, and arranged and filed so they can be referred to at a moment's notice. The blanks are the medium to give the cooperation between the teacher, nurse, and doctor, so they can closely follow each other's work without friction. The work has many responsibilities, and each should assume his part. The teacher is to recognize each day the pupils who require the attention of the attending physician. A contagious disease, whether diphtheria, scarlet fever, or a contagious skin disease like scabies or ringworm, should not remain in the class several days before it is sent to the doctor for diagnosis. The doctor can bring the teachers in closer contact with his work by an occasional talk when they hold their monthly teachers' meeting. Before beginning the day's exercise the teacher should go through her class and note which pupils she is to send to the doctor.

The following system of medical inspection with trained nurses is based on using but one card and one blank. Some of these index cards are in each classroom. Each morning the teacher fills out for each pupil she desires examined by the inspector that part of the card above the dotted line. This may seem as though more clerical work is being shifted on the already overworked teacher. But a moment's reflection will prove it saves her time, trouble, and responsibility. Many of the younger pupils do not know their name, address, and number of classroom, much less why the teacher sent them to the doctor. This necessitates the return of the pupil to his class with a note requesting the desired information, which is eventually written on any scrap of paper, to again be copied by the doctor, and a third time by the nurse. I have heard teachers say, "Who wishes to go to the doctor?" There are a few shiftless pupils who are only too ready to accept such an invitation to get out of the classroom. With the teacher answering the question, "Why sent to medical inspector?" this imposition is avoided.

In schools having a system of bells, the physician on visiting the school rings the bells on each floor a number of taps, which informs the teachers of his presence. Immediately the children are sent to him with their respective cards. In schools having no bells, each morning the teachers send to the principal's office the cards of children to be examined, and the inspector sends to the classes for these pupils. The diagnosis and disposition of the case are written on these same cards, which are then kept in the office.

Each pupil sent to the inspector for examination receives one of the following slips to take back to his teacher:

To Teacher:—

This child is referred for treatment to .....

NURSE  
DISPENSARY  
FAMILY PHYSICIAN.

This child is ..... excluded from the class room until you receive notice for his (her) return.

S. W. NEWMAYER,  
Medical Inspector.

School, *Jas. Campbell*. Teacher, *R. E. Saunders*, Room No. 7.  
Name, *William Brown*. Address, *732 Bainbridge St.*  
Date, *Jan. 8, 1908*. Sent to Med. Insp. for sores on face.

Diagnosis—*Impetigo*.

Referred to physician—Dispensary—Nurse.

Excluded—date ..... Returned .....

Treatment by nurse—at home—at school.

*Antiseptic ointment*.

(3) Dates of treatment—*1/8, 1/9, 1/10*.

Results—Cured, *1/10/08*.

Improved.

Not improved.

S. W. NEWMAYER,  
Medical Inspector.  
A. L. STANLEY,  
Nurse.

On these slips the doctor underscores whether the pupil is to go to the nurse, dispensary, or family physician for treatment, or whether excluded from the class. This admits of no mistake by the teacher, and aids her in knowing the exact nature and disposition of each case. The child cannot go home for the remainder of the day, when he was instructed to wait for treatment by the nurse, and, again, a child excluded cannot return to his seat in the classroom and the teacher remain ignorant of his exclusion by the inspector. It admits of the principal having a full written record of the disposal of all cases sent to the doctor.

When the case is referred to the nurse, the doctor specifies on the card if the child is to be treated at home or at school, or both; also the treatment recommended. This concise written report makes mistakes impossible, and may prove valuable if legal or other questions arise. These cards are filed in the office in a box with three compartments: 1, New cases; 2, unfinished cases; and, 3, cured cases. Each of these compartments is arranged according to the number of classrooms.

The nurse, on visiting the school, first takes all cards in the compartment of new cases, and sends for each pupil individually. The information on the card makes it possible for her to perform all her work without troubling the principal or teachers. After attending to the new cases and recording on them the date of treatment, she replaces them in the cabinet, in the compartments of unfinished or cured cases. She now looks over the unfinished cases and sends for those requiring treatment, again recording the date. She so proceeds each day until the child is cured or disposed of, when she records the date of cure, when the card is filed in the third compartment. Once a month all finished cards are sent to the Bureau of Health or Bureau of Education, where they are filed in a cabinet according to school and

disease. One can readily see how easy it would be to refer to these records. For example, should one desire to know how many cases of defective vision were treated and obtained the necessary glasses, or the average number of treatments required at school to cure a certain skin disease, these facts can readily be obtained.

The following are copies of weekly reports of the nurse which are successfully used in the city of Philadelphia:

A. A. CAIRNS, M. D.

CHIEF MEDICAL INSPECTOR

Dear Sirs:—

The following is a weekly report of Nurse of Schools of Fourth Section.

### THE CLINICAL LABORATORY OF THE GENERAL PRACTITIONER.\*

By MALCOLM MACKAY, B. A., M. D., C. M.,  
Windsor Mills, Quebec, Canada.

"A room fitted up as a small laboratory, with the necessary chemicals and a microscope, will prove a better investment in the long run than a static machine or a new fangled air pressure spray apparatus."—Osler.

That a laboratory is needed in the daily work of a general practitioner no one will deny, but the ideas of what should be attempted and what omitted in routine work vary greatly with the individual physician.

Some go so far as to state that they prepare and cut paraffin or celloidin sections, and make microscopical slides. Some that they do not even venture to stain for the all pervading tubercle bacillus. Others, again, will acknowledge that they do not look through a microscope from one year's end to the other.

I believe that one reason for the lack of attention to this most important branch of our work is that

the majority of books speak of tests and reagents in an abstract way and do not give definite methods for keeping the laboratory in good working order, ready for instant use, without any delay for the purpose of making up new stains and reagents which have gone bad since they were last used. It is therefore with no apology for my subject that I bring before you one man's idea of a practical laboratory well within the reach of every one, together with a few words on the actual manipulations.

If there is any who is not convinced of the use of such a laboratory I confidently refer him to an article by Dr. R. N. Willson, which appeared in the *New York Medical Journal* of September 28, 1907, and which takes up this side of the question in a very convincing way.

In the first place, a microscope is essential. No analysis of any of the secretions or excretions is complete without a microscopical examination, and no man can consider himself to be carrying on a modern practice unless he is able to intelligently carry out such an investigation. One would think that at the present stage of development of medical science that such a statement would be unnecessary, but when one sees time and again offices and dispensaries guiltless of such an instrument, except possibly one kept for show, the fact cannot be too strongly insisted upon.

Two objectives, say a 3 and a 6 or 7, will give fair results, but if bacteriology is to be attempted an oil immersion lens will be required.

Taking up, in the first place, the examination of blood, we find that for its detection in small quantities few tests are more satisfactory than the hæmin test, for which all that is required is common salt and glacial acetic acid. Frequently the guaiacum test is more convenient, and it is best to keep it in the form of gum and make up the tincture as required, using a fresh preparation of hydrogen peroxide to complete the test. The microscope will of course reveal blood, provided that the corpuscles are not disintegrated. Slides, and perhaps cover glasses as well as Canada balsam, will be required for the making of smears. In order to fix the blood before staining, the old method of using equal parts of alcohol and ether for several hours will give excellent results, but I have found that a few drops of wood alcohol poured directly on the slide will fix within a minute and give a perfect picture. The eosin staining may be taken up along with this process by adding the stain to the wood alcohol. I have never seen this method of fixing in any textbook, although doubtless the principle is the same as that upon which Wright's modification of Leishman's stain, or Jenner's stain, is based, methyl alcohol being the fixing agent. Fixing by heat has in my experience to be very carefully done in order to get any satisfactory results. For staining purposes an aqueous or alcoholic solution of eosin will keep indefinitely, and I have found that Ehrlich's acid hematoxylin,

1. Haematoxylin	2. 10 per cent.
Absolute alcohol, .....	.60 cc.
Glycerine, .....	.50 "
Water, .....	.60 cc.
Ammonia, .....	1.00 "
Alcohol, .....	1.00 "

thus prepared, the solution will keep almost indefinitely, and this can be kept in the bottle of Dole-

\*From the lecture course at the request of Dr. J. H. T. Mackay, Windsor Mills, Quebec, Canada.

field's hæmatoxylin, which keeps better than the majority of such preparations.

Methylene blue may be used as a nuclear stain, and I have found it convenient to keep a saturated solution (alcoholic) in stock, to be diluted as follows:

Löffler's blue:

Saturated alcoholic solution, .....30 c.c.;  
Solution 1 in 10,000 caustic potash in water, ..100 c.c.

Kühne's blue:

Saturated alcoholic solution, .....10 c.c.;  
5 per cent. carbolic acid water, .....90 c.c.

Ordinary staining:

Saturated alcoholic solution, .....1 part;  
Water, .....9 parts.

To examine for hæmoglobin there is no doubt that Dare's instrument is the neatest and quickest of the translucent methods, and with a little experience results soon become consistent, but the Tallquist hæmoglobin scale is by far the easiest and cheapest of all ordinary tests, and is almost, if not quite, as accurate as any of the others. It simply consists of a series of colored plates with which the blood, sucked up on a specially prepared absorbent paper, is compared.

Wetherill's scales are similar in design, but contain plates for the comparison of urine, fæces, moisture (perspiration), and post mortem blood.

For counting the blood cells the Thoma-Zeiss apparatus is probably the most popular, and is accurate when the technique is good. But it must be remembered that the count cannot be relied upon until the procedure has been carried out for a number of times. The solutions, which can easily be made in the laboratory, are as follows:

Toison's solution for counting the red cells:

Distilled water, .....160 c.c.;  
Neutral glycerin, .....30 c.c.;  
Sodium sulphate, .....8 grammes;  
Sodium chloride, .....1 gramme;  
Methyl violet 5 B., .....0.025 gramme.

This must be filtered before use, as a mould quickly grows in the solution.

For counting the white cells:

Glacial acetic acid, ...0.5 per cent. solution in water;  
Methylene blue, .....q. s. to color.

The physician omits one of his greatest aids in a doubtful diagnosis when he neglects to make a blood count, for when compared with a blood slide and differential count it will often turn a possibility into a certainty. Yet how often men outside of the hospitals make a practise of carrying out this comparatively simple procedure?

The Widal test, as performed with dead cultures, has given fair satisfaction, and the test can easily be obtained through some of the pharmaceutical houses.

It may be performed in bulk or microscopically, and saves one taking a culture from a stock tube and using an incubator.

The examination of urine requires litmus paper, a urinometer, a pipette, test tubes, alcohol lamp or Bunsen burner; nitric and acetic acids for the ordinary tests for albumin; and Esbach's albuminometer and solution (picric acid, 1 gramme; citric acid, 2 grammes; water, 100 c.c.) for the quantitative estimation.

Fehling's solution for detecting sugar should be kept in the form of two solutions, keeping the copper apart from the alkali. A yeast saccharometer gives a fair estimate of the quantity in a given specimen.

For the quantitative determination of urea the Doremus ureometer is generally used. The sodium hydroxide solution (6 ounces to 1 pint water) should be kept in a rubber stoppered bottle separate from the bromine until the test is actually being made. Then it is poured into the apparatus until it reaches the mark, when 0.1 of its volume of bromine is added. The addition of water to fill the tube is followed by the introduction of 1 c.c. of urine by means of the pipette, the resulting nitrogen being read off as the index of the amount of urea.

Acetone is most easily detected by adding potassium hydrate solution to a distillate of the urine and adding a few drops of a solution of iodine in potassium iodide, the result being iodoform when the reaction is positive.

Tile may be considered to be present when, placed alongside a drop of nitrous acid on filter paper, the urine shows the play of colors so often described. Ehrlich's diazo reaction is easily performed by keeping in stock two solutions:

- I. Sulphanilic acid, .....1 part;  
Hydrochloric acid, .....50 parts;  
Aq. destil., .....1,000 parts.
- II. Sodium nitrite, .....1 part;  
Aq. destil., .....200 parts.

In addition, there is required some liquor ammonia. Personally I never obtained much satisfaction with this test in the early diagnosis of typhoid fever. For one year it was carried out daily in 166 cases. Less than forty per cent. showed the reaction at any time, and it practically never appeared before the second week. Others have had better results than this; but few authorities show much enthusiasm at the present time.

Indicanuria is detected most surely by taking 10 c.c. of urine, 10 c.c. of hydrochloric acid (c.p.), and shaking up with 25 drops of 0.5 per cent. solution of potassium permanganate. Adding 5 c.c. chloroform and shaking will bring down a purple coloration followed by a blue deposit, provided that indicanuria is present.

A centrifugal machine is a very useful instrument to have in the laboratory, but, contrary to the opinion of some, it is not essential to the study of urinary sediments. Use a conical glass, keep the urine cool, take plenty of it, and let it stand for from six to eighteen hours, and very little will be missed. A little salicylic acid will in summer time be found a useful addition to prevent decomposition.

Looking for tubercle bacilli is at the best a tedious affair, and without a centrifuge is desperately slow, but by letting the urine stand for a day, then pouring off all but the sediment, adding distilled water to the original volume, shaking, and repeating the process several times, one can get a good slide, but one must be very careful of the technique and beware the deceitful smegma bacillus.

The gastric contents present a field explored by surprisingly few general practitioners, considering

that the apparatus and reagents required are but few, and the methods simple. Once the contents are removed, a glass funnel with filter paper soon gives a clear solution, which should be tested at once with litmus paper. A burette filled with a decinormal solution of sodium hydrate (4 grammes in 1,000 c.c. distilled water) when carefully titrated into a given volume of stomach contents containing a little phenolphthalein (one per cent. alcoholic solution) gives the total acidity.

Congo red paper will detect free acids, though a large amount of combined hydrochloric acid also gives this reaction.

To test for free hydrochloric acid a 0.5 per cent. alcoholic solution of dimethylamidoazobenzol is very simple and delicate, and as it is used in the quantitative examination of free hydrochloric acid it is to be preferred if but one reagent is used.

The tests for acetic and butyric acid require no special reagents, while lactic acid may be detected by the old carbolic acid and ferric chloride method or by the new technique described by J. L. McPhedran, of Toronto.

The microscopical examination of gastric contents as well as of faeces requires no additional apparatus, and often gives a clue to an obscure diagnosis.

A glance at the sputum is at times sufficient to point to a diagnosis in certain pulmonary conditions, but a microscopical examination is infinitely more satisfactory and indeed is most conclusive when we get a positive result—and most aggravating when we do not. After pouring out the sputum into a Petri dish and separating it with hat pins or a platinum wire, it will often be found useful to spread it out on an ordinary pane of window glass and examine it with a hand lens. Another plan is to pour it out upon the black paper which is wrapped around photographic films or plates. The peculiarities of the specimen can be easily seen on this background, and the whole can be thrown into the fire to insure complete destruction of any bacilli which may be present.

Make a saturated alcoholic solution of methylene blue and one of fuchsin as stock ready for dilution to stain the slides. In staining for tubercle bacilli the solution of fuchsin is diluted one in nine in a solution of carbolic acid (20 per cent.). While staining, heat to boiling, decolorize with 25 per cent. sulphuric acid, and counterstain with methylene blue. It is often important to use absolute alcohol as a decolorizing agent in addition to the above, as it renders the distinction between the tubercle and smegma bacillus rather more certain.

In staining for other organisms aniline gentian violet must be used, but in order that it may keep it is best to have a saturated alcoholic solution of the gentian violet in a separate bottle. When required for use, add to four parts of the alcoholic solution twenty-one parts of aniline water (5 per cent. solution of aniline oil in water shaken and filtered). It is well not to use this solution for several hours on account of precipitation. Gram's iodine is easily made by adding to 100 c.c. distilled water one gramme iodine and two grammes of potassium iodide. Safranin keeps well in a satu-

rated solution, and is one of the best counterstains we have.

In regard to the detection and classification of ordinary pathogenic bacteria it is wonderful what satisfactory results can be obtained by cultures in bouillon, gelatin, white of egg, and potato, incubated in a plate warmer of a kitchen range or some similar contrivance. It is not very often that such an examination need be carried out by the general practitioner, but the identification of diphtheria bacilli by the method of culture on the white of an egg may be accomplished by anybody, and will give most satisfactory results. Its main feature is its simplicity, nothing being required but a hard boiled egg and an egg cup. Take the swab from the throat in the usual way, and after breaking off the shell at one end of the egg, make a smear for incubation. Place the egg inverted in the egg cup, and put it in a warm place, and in nine to fourteen hours a diagnosis can be made from the culture, as no other germ grows with such rapidity in this medium. If left over twenty-four hours it is likely to be overgrown by other bacilli or cocci. A slide from one of the colonies will show vast numbers of the bacteria if stained with Löffler's blue or some distinctive stain. For a country practitioner this method is simply invaluable, and much time is saved by making a smear from every suspicious throat at the first visit.

For the study of transudates and exudates as well as cystic and cerebrospinal fluid, the reagents I have mentioned are generally sufficient, though possibly a saturated alcoholic solution of Sudan iii may be of use in detecting fats. It is well in these cases to stain at least one slide for tubercle bacilli, one with eosin and hæmatoxylin, one with methylene blue, one by Gram's method, and one with Sudan iii. This series of stains will show practically everything bacteriologically and cytologically that can be seen in such slides.

In conclusion there should be a day book on the laboratory table ready to receive notes of tests as they are made, whence they may be transcribed to the case reports at leisure. In addition, all permanent slides should be labelled and stored away in boxes made for the purpose, where they will in time form a valuable collection for reference.

A laboratory such as I have described will clear up the diagnosis in at least 50 per cent. of the cases which puzzle the man who does not think of doing anything more than testing the urine for albumin and sugar, and will save a great deal of time for the country practitioner, who anxiously waits, possibly for days, for the report on the sputum, blood, or smear he has sent for examination to the board of health, a hundred miles away.

## LACTACID MILK IN INFANT FEEDING.

BY CHARLES EDGERTON CARTER, M. D.,  
New York,

Instructor in Medicine, Department of Pediatrics, Postgraduate Medical School.

The problem of duplicating Nature's formula is the point about which the whole subject of infant feeding has centered even before the time that Rotch first presented percentage methods of milk modification. Quantitatively it may be possible to dilute, add, and combine until the product is similar to that of Nature's laboratory, but chemically and bacteriologically the problem is far more complex; in consequence of which attempts have failed to produce a milk food identical with or even similar to the natural product in its enzymic activity and nutritional value. Following the investigations of Rotch, Holt, Cailé, Chapin, Winters, and others in our country, practical clinicians admit that in modifying cows' milk for infant feeding we are merely producing the best practical substitute which conditions permit. That we fall far short of Nature's human product is frankly granted. Past experiences with buttermilk feedings have proved equally unsatisfactory. On account of the difficulty in procuring, as well as the extreme variability in bacterial content, no system of extended buttermilk feeding has been elaborated. Therefore, in advocating a system of feeding based upon the modification of cows' milk, which has been fortified by the lactic acid ferment, we offer of necessity still a substitute, but not an attempted reproduction of human milk. We are dealing with a natural milk augmented by microscopical life, in place of an inert medium loaded with its sterilized dead. To suggest that by this method we may have at hand a means of most effectually overcoming certain difficulties in feeding and of preventing intestinal malassimilation and intoxication, is the purpose of this necessarily diagrammatical paper.

For the purpose of condensation, the term "lactacid milk" is adopted as a name for fresh cows' milk, which has been artificially impregnated with the "*Bacillus bulgaricus*" and has become in consequence a fermented product with definite parasitic inhibitory properties and an easily assimilable casein curd. The detailed method of acquiring this artificial product, as well as the process of its final adaptation to the infant's requirements, will be elaborated later in this article. For the present we may consider lactacid milk as an entity in substitute feeding.

The literature available on buttermilk feeding, corroborated by personal observation, discloses its following shortcomings, viz.: 1, Commercial buttermilk contains little or no fat; 2, it varies in the amount of its component elements on account of an equally variable degree of dilution; 3, it presents a food teeming with extraneous germs of filth or disease; 4, it is impossible to procure, at stated intervals, in required amounts; 5, finally, it is an inexact, unhygienic base for even temporary milk substitution.

On the other hand, the vital factor in buttermilk which has made it seem desirable as a food, and which has rendered it efficacious as a remedy, is

found in the lactic acid ferment. This ferment today has been isolated, cultivated, and, like the housewife's yeast, is available in convenient form for household use. Thus it is possible to give our difficult feeding cases, infant or adult, food not alone efficient in itself, but augmented by an active agent for overwhelming the pathogenic bacteria that may inhabit the intestinal tract. Like the blood stream, which carries not only food for the tissues, but also manifests the defensive phagocytic function, we have in lactacid milk a food medium inimical to all undesired fermentative process and possibly prohibitive of pathogenic growth. From what evidence do we infer that lactic acid may inhibit pathogenic germs in the intestinal tract? Herter (*British Medical Journal*, December 25, 1907) writes that lactic acid bacilli notably decreased intestinal putrefaction due to *Bacillus coli*, or *Bacillus proteus*; M. Cohendy reported (in *Archives de la Société de biologie*, November 17, 1906) that, from personal ingesta of pure bacilli lacti, intestinal putrefaction was markedly decreased, and, furthermore, these results persisted for seven weeks after cessation of the daily augmentation from the ingested cultures. Pochou, of Lausanne, reports similar results. His urine analyses showed great diminution of indol and phenol substances, which are accepted as certain indices of intestinal putrefaction. Metchnikoff concludes "that lactic acid bacilli prevent multiplication of other microbes, but are incapable of destroying these pernicious microbes." Should continued clinical results demonstrate the accuracy of such observation when applied to lactacid milk, it is rational to hope that the natural powers of resistance may more frequently win in their struggle against typhoid or even tuberculous infection of the intestines; provided we are able to decrease to any appreciable degree the fermentative and putrefactive processes of the digestive tract.

Heim states that typhoid bacilli succumb after forty-eight days when the culture is impregnated with lactic acid bacilli. Piffard has also found that the *Bacillus bulgaricus* (from Bulgarian sour milk) inhibits the growth of typhoid bacilli on dextrose broth, markedly so within one week's time. Considering the acknowledged vitality and longevity of the typhoid germ, this possibly inhibitory value of lactic bacilli in the intestine is obvious. More than that, Cohendy's comment upon their persistence seven weeks after ingestion, shows that the lactic acid bacilli in all probability adapt themselves to the anaerobic habitat of the intestine and feeding upon the carbohydrates digested, may further preserve organic matter from putrefaction. As to the tolerance of lactic acid which the human organism exhibits, it has been found that twelve grammes can be taken by mouth daily, without untoward effect. While experience has shown that moderate use of lactic acid is not provocative of rachitic changes in bone and muscle, as formerly taught, yet possible individual idiosyncrasies may occur. On the contrary, Tigersted (*Physiology*, p. 297) states that lactic acid is normally elaborated in the human metabolism as a result of the action of pancreatic juice and bacteria, upon carbohydrates in the small intestine.

To contrast with the persistence and elaboration of lactic acid in the intestine, M. Copelan's has found that the bactericidinhibitory property of fresh milk becomes inactive after four hours. This bactericidinhibitory property of strictly fresh milk is of such short life then that it may be ignored absolutely as an aid in fortifying against infective invasion. On the other hand, the inhibitory feature of lactacid milk may well be considered when we realize that 72 per cent. of all herds in New York State is infected with tuberculosis, according to V. A. Moore, of Cornell University. With an annual mortality of children under one year of 16,500 in New York city, we need to utilize every rational, available method to better these conditions.

In seeking to adapt lactacid milk to a practical utilization it is desirable to avoid what Chapin so well calls "freak or random feeding," and yet that need not be such a difficult matter when we recall the complexity of some percentage feedings. Test tube and laboratory estimates must be verified by long clinical observation before any method of body building can graduate from the awkward squad of "freak feeding," and lactacid milk may be diluted or adapted to the basis of percentage feeding according to the requirements of existing conditions.

It is appreciated that sufficient proteid of assimilable form is required for normal infant growth. That perfect digestion does not necessarily mean complete assimilation is also recognized. Therefore, an important argument in favor of lactacid milk feeding lies in the easily assimilable casein curd of the proteid. Since an excess of proteid in the intestinal tract, whether that be in excess for the type or for the individual, can be determined only when putrefactive processes ensue, the introduction of lactacid milk carrying an antiputrefactive enzyme, robs excess proteid ingesta of its dangers. Further, from this fact, it also follows that in pathological conditions of uric acid excess, with the accompanying faulty metabolism, a diet that includes lactacid milk is indicated both as an anti-fermentative and antacid.

The technique and detail of lactacid milk modification may be given best, perhaps, by reproducing the printed leaflet used in my clinical work at the Postgraduate Hospital. This may be taken in three steps, namely: First, the preparation of lactacid milk; second, the modification of this prepared milk to any desired formula; and, third, number and quantity of daily feedings:

#### TO PREPARE LACTACID MILK.

1. Pour one quart fresh bottled milk into clean pitcher.
2. Add .... glassfuls of hot water.
3. Crush one tablet and stir with clean spoon into milk.
4. Add pinch of salt.
5. Cover with clean napkin and set in warm (not hot) place for twenty-four hours.
6. After twenty-four hours keep on ice or, in cold weather, out of doors.

N. B.—Enough for two days. Prepare fresh every other day.

#### TO PREPARE DAILY FEEDINGS.

1. Stir lactacid milk with clean spoon and mix feedings for day as follows:
2. Pour .... oz. of lactacid milk in clean quart bottle or pitcher.

- |                             |   |                   |                 |           |        |        |           |
|-----------------------------|---|-------------------|-----------------|-----------|--------|--------|-----------|
| 3. Add .... oz.             | <table border="0"> <tr> <td>Barley water</td> <td rowspan="5">} to this milk.</td> </tr> <tr> <td>Oatmeal "</td> </tr> <tr> <td>Rice "</td> </tr> <tr> <td>Lime "</td> </tr> <tr> <td>Albumin "</td> </tr> </table> | Barley water      | } to this milk. | Oatmeal " | Rice " | Lime " | Albumin " |
| Barley water                | } to this milk.   |                   |                 |           |        |        |           |
| Oatmeal "                   |   |                   |                 |           |        |        |           |
| Rice "                      |   |                   |                 |           |        |        |           |
| Lime "                      |   |                   |                 |           |        |        |           |
| Albumin "                   |   |                   |                 |           |        |        |           |
| 4. Add also .... oz.        | <table border="0"> <tr> <td>granulated sugar.</td> </tr> <tr> <td>milk sugar.</td> </tr> </table>   | granulated sugar. | milk sugar.     |           |        |        |           |
| granulated sugar.           |   |                   |                 |           |        |        |           |
| milk sugar.                 |   |                   |                 |           |        |        |           |
| 5. Stir well and put on ice | until needed.   |                   |                 |           |        |        |           |
| 6. Feed of this mixture     | .... oz. every .... hrs. heated to body temperature.  |                   |                 |           |        |        |           |

N. B.—Enough for one day.

#### Resumé.

1. Lactacid milk is obtained from clean, fresh cows' milk, fermented by the lactic bacillus, isolated by Cohendy in 1903, and which he describes as "not growing under 35° F. nor above 63° F." The degree of acidity is limited by the time allowed for the activity of the bacilli.

2. Buttermilk feeding and lactacid milk feeding are absolutely distinct. The former affords an uncertain and temporary expedient always, and being a spontaneously sour milk contains, besides the lactic ferments, generally yeasts which produce alcohol.

3. In infant feeding the frequent desideratum of high proteid percentages may be found not only possible, but also safe, with lactacid modification of milk.

4. The digestive enzymes of natural milk are not killed as in the unnatural processes of sterilization or even in Pasteurization, but are augmented by the *Bacillus bulgaricus*.

5. Lactacid milk is logically indicated in children: a, In difficult feeding cases; b, in fermentative diarrhœas; c, in specific enteric infections of typhoid or tuberculous bacilli.

6. From the extremes of the scientist and the enthusiast, from Herter and from Metchnikoff come corroborative evidence that lactic acid inhibits intestinal putrefaction.

7. Promulgation of the general desirability of undiluted lactacid milk as a beverage can but lessen the ills that flesh is heir to, even if it cannot accomplish, as Metchnikoff hopes, the prolongation of man's allotted span.

8. The writer presents this as a preliminary communication, and will later submit a series of results obtained in indicated cases of lactacid milk feeding.

54 WEST FIFTY-SECOND STREET.

**Gunshot Wounds.**—In *Der Militärarts*, Dr. Kerchenberger gives a study of gunshot injuries on post mortem cases and also on the healed injuries of attempted suicide cases. He calls attention to the action of powder gas and discusses its action in general and more specifically when shot into the mouth and into the jaw. The action of the projectile alone is not so destructive. The blowing out of the brain from the cranial cavity he attributes to the action of powder gas. The powerful rushing in of the air behind the projectile may also play a part. The action of the gas is especially important in shots of the mouth. As signs of powder gas having entered the bullet wound, Kerchenberger gives the following: 1. When the bullet wound is larger than the caliber of the gun. 2. A widespread destruction of the tissues. 3. Fractures of several ribs. 4. Blackening of the internal organs by smoke of the powder.—*The Military Surgeon*.

## Our Readers' Discussions.

### A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far as they have been decided upon, the further questions are as follows:

LXXXII.—How do you treat fracture of the patella? (Closed March 16, 1908.)

LXXXIII.—How do you treat seasickness? (Answers due not later than April 15, 1908.)

LXXXIV.—How do you treat sunstroke? (Answers due not later than May 15, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisors will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL.

The prize of \$25 for the best essay submitted in answer to question LXXXI has been awarded to Dr. Frank B. Kirby, of Philadelphia, whose article appeared on page 594.

### PRIZE QUESTION NO. LXXXI.

#### HOW DO YOU TREAT GALLSTONE COLIC?

(Concluded from page 599.)

Dr. Richard Lightburn, of Kansas City, gives his opinion as follows:

In gallstone colic treatment is instituted for two purposes, the relief of pain and the removal of the cause.

The suffering is best combatted by the hypodermatic administration, every half hour, of small doses ( $\frac{1}{8}$  grain) of morphine sulphate, together with strychnine sulphate ( $\frac{1}{120}$  grain). At the same time a tablet of amorphous hyoscyamine ( $\frac{1}{250}$  grain), in an ounce of hot water, is given by the mouth, to be repeated in thirty minutes.

As a rule the patient rests comfortably after the second dose, and the remedies need be repeated only every three or four hours. A few whiffs of chloroform will serve to lessen the pain while the initial doses are being absorbed.

This combination, in my hands, has proved more efficient and satisfactory than the heroic amounts of morphine, alone or with atropine, so frequently employed. The disagreeable, sometimes serious, after effects of the heavy dosage are avoided, and, if the attacks are of frequent occurrence, the risk of contracting the drug habit is materially lessened. Fomentations, locally, or hot baths, the water being at as high a temperature as can be borne; will often prove valuable adjuvant measures.

The second condition, the removal of the cause, is most satisfactorily met by cholecystotomy. In competent hands the danger is slight and relief practically certain.

In case the patient refuses to undergo an operation the only course open is the administration of remedies which will aid Nature in getting rid of the concretions. Here the alkalies are of greatest value. Of these, sodium phosphate, a drachm dis-

solved in hot water and taken before breakfast, daily, is the best. I also give sodium succinate, five grains after each meal, continuing it for several months.

Starchy, fatty, and saccharine foods are to be avoided, and plenty of outdoor exercise is of great importance.

Dr. Mark H. Sears, of Denver, Colorado, says:

The pain and nausea of gallstone colic varies all from a hardly noticeable uneasiness to the paroxysms of a choked, or partially choked, duct, through which Nature is endeavoring to force a stone that frequently is too large to pass. It will usually be located in the right hypochondrium or in the epigastric region.

Very often there accompanies a decided yellow tinge of the skin, the sign of bile absorption, which may have preceded the attack for several days, or, as frequently happens, this symptom may be conspicuous by its absence.

Between these two extremes of severity, slight in the one instance, or the agony of the other, we must seek for and apply a remedy, which will relieve the symptoms of irritability, assuage the unbearable pain, and give rest and comfort to the sufferer. Be sure of your diagnosis. Do not confound the colic of the gallstone with the nephritic stem or other varieties of abdominal distress, location, severity, history, palpation, the presence or absence of elevation of temperature, or any other symptom, which may throw light upon the condition, should, be considered carefully. Nor should the masking symptoms of a neoplasm growing at or near the pyloric orifice of the stomach or at the head of the pancreas be overlooked. They should be carefully considered and excluded. A growth of this kind very often causes symptoms much resembling the distended gallbladder of a closed duct, especially if accompanied with pain and jaundice.

If the call for aid is very urgent, nothing has thus far been used which affords the relief given by the hypodermatic administration of morphine. It should be given in quarter, third, or, in very severe instances, half grain doses. The effect of the remedy should be carefully watched, and not repeated without good reason. If it is necessary to relieve the awful suffering, until various methods of medication have time to act, if for any reason they are slow in doing so, equal parts of chloroform and water poured on a flat sponge and applied over the seat of the pain will give a grateful, although only temporary, relief until more efficient and permanent remedies can be used. A few whiffs of chloroform itself will often bridge a crisis.

Great comfort will be experienced from the use of the hot bath, as hot as can be borne, but not to be continued so long as to act as a depressant. The hot water bottle is a valuable remedy also. Steaming the region of the liver is another method of applying heat, and any home which affords a tea kettle will be amply provided with apparatus. Hot fomentations, notably the flaxseed, poppy leaf, or hop stupe, will often abate the pain, and give the gallstone the opportunity to either proceed into the intestine or recede into the gallbladder.

The use of olive oil in large doses, accompanied by laxatives, has also found favor in the past, and is still used more or less, but is of doubtful utility. It was formerly thought that by using certain remedies it would be possible to dissolve gallstones, and sulphuric ether and oil of turpentine in proper dosage have long enjoyed this reputation, but they have proved disappointing and of little or no permanent value.

Sodium sulphate and sodium phosphate, the latter in saturated solution, and given in drachm doses, have shown a distinct remedial action. It is believed that they prevent in some way the formation of bile concretions by modifying the concentration of that fluid, or perhaps allaying catarrhal conditions in the bile cyst or ducts. For the intolerable itching that occurs in some cases, alkaline baths have been used. Sodium bicarbonate and sodium biborate have entered largely into this form of medication. Powdered starch applied to the skin is another remedy. It is soothing and valuable. An ointment containing menthol and ichthylol has afforded much relief in the writer's hands. These forms of medication can be extended indefinitely. Wool fat should always form the base of ointments likely to ferment.

The diet in these cases should be simple. Saccharine and starchy foods should be taken in moderation, while meats should be boiled. The bowels should be kept free by the use of the laxative alkaline mineral waters, moderate depletion of the portal circulation being the aim. The habits of life should be simple and regular, and the daily muscular exercise sufficient for the bodily needs, but in no way exhausting. It should not be forgotten that each individual case will present characteristics peculiar to itself. These should be met by modifications of treatment which will meet the conditions. In this manner recurring attacks of gallstone colic may be successfully passed, and much of a lifetime spent, with only an occasional attack. The bile passages are very tolerant, and the gallstone may exist in large numbers, without causing any symptoms whatever. The case will be very different and much more serious when constantly recurring attacks of colic render the life of the sufferer miserable. In this event surgical interference should be seriously considered. When, however, the cystic or common ducts become clogged surgical relief becomes imperative, and an operation should be undertaken immediately by a competent surgeon. The results of this operation are very satisfactory, and when practised with careful attention to the technique, which the operation demands, they are secured at once, with a minimum of danger. Any recent textbook will give the details.

Dr. Samuel J. Saxt. of Philadelphia writes:

The treatment of gallstone colic depends on the severity of the attack, which, on the one hand, may be mild and last only a few hours, while, on the other hand, it may continue anywhere from a few days to a week or more.

It is well to commence with a hypodermatic injection of morphine, 1/4 grain, accompanied by a 100

grain atropine. The morphine relieves the pain and the atropine relaxes the muscular coats of the gallbladder and the appendages thereof, thus aiding the stone to escape. I repeat this dose three or four times, at intervals, until the pain ceases. In addition, I give a few whiffs of chloroform inhalations until the effect of morphine takes place, and this invariably gives the patient relief. A very valuable adjunct is hot applications over the hepatic region. The applications should be a little above the temperature of the normal body, and continued long enough until the rigidity of the muscles of this region is well relaxed. The writer finds that gratifying results are obtained with hot turpentine stupes.

Some lay great stress on hot baths. I, however, find that it not only fails, but instead is an inconvenience to the patient. In one case where I resorted to this measure the heart action became so depressed, the pulse so weak, that I was compelled to use vascular stimulants to restore the heart's action.

Olive oil in some cases is very beneficial. It is best given in one large dose, two to four ounces. It increases the flow of bile, and thus aids materially the escape of the calculi.

If the patient complains of nausea and vomiting it is best not to give the oil, for the gallbladder at this time is no doubt very much irritated and inflamed, and the strain in producing the vomitus may cause rupture of the organ. Nausea and vomiting may be relieved by administering brandy with cracked ice. If this fails I give the following with happy results:

R Cerii oxalatis, .....	gr. xxiv;
Bismuthi subnitratii .....	gr. xxxvi;
Sodii bicarbonatis, .....	5ii
Mix. Chartae No. xii.	
Signat. One every hour until relieved.	

If the case is mild it is unnecessary to resort to the afore mentioned measures, and in such cases very often the attack will yield to codeine and acetphenetidin in capsule form.

Regarding purgatives and cholagogues in gallstone colic, I cannot too strongly emphasize that they should not be thought of during an acute attack. They not only increase the severity and duration of the attack, but may in their strong action upon the gallbladder (the time when it is most inflamed and least resistant) cause rupture of same. If, however, the liver is very torpid, calomel in small divided doses may be given.

The question of surgical interference during an acute attack should not be considered until the period of quiescence.

*Conclusions.*—I will terminate my brief remarks by stating:

1. Keep the patient at perfect rest in bed.
2. Make subcutaneous injections of morphine and atropine, followed by chloroform inhalations.
3. If there is nausea and vomiting present, relieve same by measures indicated.
4. Apply hot applications with counter irritation over the hepatic region.

5. Avoid purgatives and cholagogues. They should be given between the attacks with the hope that the irritation of the gallbladder will be diminished.

6. Take into consideration the prophylactic measures after the acute attack is over, for much can be accomplished to prevent the formation of biliary calculi.

*Dr. Lawrence M. Hynson, of Washington, D. C., observes:*

The treatment of simple cases of gallstone colic presents at first sight no striking difficulties, but in prolonged and severe cases it may be necessary to direct the treatment of the colic to the treatment of the general condition of gallstones (cholelithiasis), for the colic is only a symptom of an existing condition.

When the patient experiences the severe paroxysmal pains produced by biliary calculi, morphine, hypodermatically, in doses of one quarter grain each, should be given without hesitation. Morphine so given relieves the severe pain, produces comfort of the patient, and allows the muscular structures of the bile duct to relax, thus permitting the calculus to pass on. Care should be taken to see that just enough morphine is given to keep the patient free from pain, for too frequently large doses of this drug might mask the symptoms resulting from the possible rupture of the common bile duct, with a discharge of the gallstone into the peritoneal cavity. The inhalation of chloroform, if at hand, may produce relief from pain in the mildly acute cases, but where the pain is severe and continuous morphine, hypodermatically, is indicated.

Rest in bed during the attack is necessary, and hot applications, hot water bags, should be applied over the liver region. Where the patients cannot bear the weight of a water bag, owing to tenderness, I have found the Japanese hand stove to be very useful in that it is very light in weight and supplies an intense dry heat.

In protracted cases it is of the utmost importance to keep the bowels thoroughly open. Daily rectal irrigations with artificial Carlsbad salts, two drachms to one quart of warm water, allowing the fluid to run in slowly and encouraging the patient to hold it as long as possible before releasing it, has an effect of producing a reflex action on the bile duct through the peristaltic motion of the lower bowel. This treatment can be enhanced by the drinking, each morning, of one glass of water containing one drachm of the artificial Carlsbad salts. When the bowels are unusually sluggish give rectal injections of glycerin, one ounce, at bedtime.

Where a series of attacks of colic have occurred and the patient anticipates another, relief from pain has been observed by administering camphorated oil (*Pharmacopœia of the United States*), five to eight drops on a lump of sugar, every fifteen minutes.

In regard to the diet the only change to make is to restrict heavy and rich food, as, for instance, salads and desserts. The eating of reasonable quantities of green vegetables, stewed fruits, stewed chicken, and chopped meat is of advantage in hastening the passage of the calculus. The drinking of a glass of hot water morning and evening will do much to overcome the gastric irritation usually accompanying such attacks.

The patient should be cautioned against vomit-

ing when it is evident, as such exertion may produce rupture of the bile duct should the stone be large and firmly impacted. The hypodermatic injection of morphine given for the pain will also minimize this tendency to vomit.

In those cases in which the attack of colic lasts for several days, and when the pain is not too severe, the patient may be allowed (provided there is no fever) to walk about the house, care being taken to prevent undue pressure or tension being made over the liver region.

In cases resisting this treatment, and where great prostration, weakness, elevation of temperature, and marked jaundice occurs, the treatment of the colic can be found only in surgical intervention.

*Dr. R. S. Fitzgerald, of Richmond, Va., states:*

During the attack of gallstone colic the indications are to relieve pain and spasm, which are very severe. Hot oil of turpentine stupes are at once applied and changed every fifteen minutes, using water as hot as patient can stand, with only two or three drops of turpentine applied to side of towel next to skin; of course these stupes are applied over the region of the liver. A few whiffs of chloroform may be necessary for dulling the pain until the morphine,  $\frac{1}{6}$  grain, repeated if necessary, has time to get in its work.

Then I use the following formula: Sodium chloride,  $\mathfrak{z}$ i; sodium sulphate,  $\mathfrak{z}$ i; sodium phosphate,  $\mathfrak{z}$ i; sodium bicarbonate,  $\mathfrak{z}$ i. Give this in a glass of water at one dose, and repeat the dose every three hours. Keep up this treatment for two or three days, and after the trouble is over put your patient on granular effervescent sodium phosphate,  $\mathfrak{z}$ ii in water before breakfast, and at bedtime, or as often as necessary to keep the bowels open. Give a good tonic of hydrargyri chloridum corrosivum, gr. i; tincture nucis vomicæ,  $\mathfrak{z}$ iiss; elix. gentian, q. s., and  $\mathfrak{z}$ iv. Teaspoonful in water before meals.

If this does not relieve take him to the hospital and remove the cause surgically.

*Dr. William S. McCormick, of Philadelphia, writes:*

In this condition the object is to secure quick relief from the severe pain. In my experience nothing has served better than to give, subcutaneously, morphine in doses of grain  $\frac{1}{8}$  to  $\frac{1}{4}$ , guarded with atropine, and then give inhalations of chloroform until the effects of the morphine are noticeable. This plan usually gives ease in a few moments.

The colic can also be relieved by the hot bath and hot applications over the liver. The temperature of the bath should be from  $98^{\circ}$  to  $102^{\circ}$  F., and continued for about fifteen minutes unless cardiac depression results and pulse becomes weak. Oil of turpentine stupes over the hepatic area are also valuable.

During the interval the patient should have a well regulated diet, mostly vegetable; systematic exercise; mineral waters; sodium phosphate in regulated doses to keep the bile flowing.

Proper attention should be given to relieve the catarrhal condition of the ducts, in order that the stones can pass without causing such severe pains.

## Therapeutical Notes.

**Formulas for Skin Applications.**—From *Die Praxis der Hautkrankheiten*, a collection of the teachings of Professor P. G. Unna, by Dr. Iwan Bloch, we take the following selection of formulas:

*Lassar's Paste:*

Salicylic acid, .....	5ss;
Petrolatum, .....	5iiss.
Zinc oxide, .....	5i.
Starch, .....	5v.

M.

*Zinc Paste:*

Zinc oxide, .....	5vi;
Precipitated silica, .....	5i.
Benzoated oil, .....	5iii;
Benzoated lard, .....	5ii.

M.

*Zinc Sulphur Paste:*

Zinc oxide, .....	5iiss;
Precipitated sulphur, .....	5iiss;
Precipitated silica, .....	5i;
Benzoated oil, .....	5iii;
Benzoated lard, .....	5ii.

M.

*Red Zinc Sulphur Paste:*

Zinc sulphur paste, .....	.99 parts;
Cinnabar, .....	1 part.

M.

*Unna's Bole Paste:*

White bole, .....	5i.
Linseed oil, .....	5i.
Zinc oxide, .....	5v.
Solution of lead subacetate, .....	5v.

M.

*Unna's Lead Paste:*

Rice starch, .....	5iiss;
Linseed oil, .....	5i.
Glycerin, .....	5v.
Vinegar, .....	5ii.

M.

*Unna's Caustic Paste:*

Potassium hydroxide, .....	
Quicklime, .....	
Green soap, .....	
Distilled water, of each equal parts, .....	

M.

*Exfoliative Zinc Paste (Pasta Lepismatica):*

Zinc paste, .....	5i.
Resorcin, .....	5i.
Ichthyol, .....	5i.
Petrolatum, .....	5i.

M.

*Soluble Adhesive Paste:*

Zinc, .....	
Starch, .....	5v.
Glycerin, .....	5v.
Water, .....	5v.

M.

*Ichthyol Dextrin Paste:*

Ichthyol, .....	5i.
Dextrin, .....	5i.
Water, .....	5i.
Glycerin, .....	5i.

M.

*Ichthyol Zinc Paste:*

Ichthyol, .....	5i.
Zinc, .....	5i.
Water, .....	5i.
Glycerin, .....	5i.

M.

*Gelanth Film:*

Gelatin, hydrated, .....	5i.
Treacanth, .....	5i.
Glycerin, .....	5i.
Distilled water, .....	5i.
Benzoic acid, artificial, .....	5i.
Rose oil, .....	5i.

M.

*Gelanth Cream:*

Zinc oxide, .....	5i.
Petrolatum, .....	5i.
Gelanth film, .....	5i.

M.

Extract jasmine, .....	5i.
Extract syringa, .....	5i.

M.

**The Treatment of Acute Bronchitis.**—Martinet (*Presse médicale*, January 11, 1908) outlines the method of treating acute bronchitis in the earlier stages of the disease. He overcomes the inflammatory condition by the application of sinapisms and poultices to the chest, the limbs being enveloped in cotton wadding. Warm baths (100° F.) are given after an acute congestive attack. To allay the cough and assist expectoration the following mixture is given:

Tincture of aconite, .....	5i.
Cherry laurel water, .....	5i.
Sodium benzoate, .....	5i.
Syrup of codeine, .....	5i.
Syrup of senega, .....	5i.
Syrup of ipecac, .....	5i.

M. Sig.: One tablespoonful every three hours.

To overcome the general infection and fever a saline purgative is given, followed by antipyretic treatment, the following cachet being prescribed:

Quinine dihydrochloride, .....	5i.
Antipyrine, .....	5i.
M. ft. cachet No. 2.	

Sig.: One cachet to be given on the first and second day at 2 o'clock p. m.

**Mercurous Bromide in Syphilis.**—It has been found, after several trials, that the following is the best solution for use as an intramuscular injection in syphilis:

Mercurous bromide, .....	5i.
Sodium bromide, .....	5i.
Distilled water, sterilized, .....	5i.

M. ft. inject.

In doses of fifteen to thirty minims this injection is said to be painless and effective in action.

**Hypophysial Opothrapy.**—The part played by the hypophysis in the economy seems to have great importance. It appears to influence nutrition to a certain degree, as shown by the changes in it in acromegaly, and it is this function of which use has been made in infectious diseases by Louis Remy and Arthur Doble. The results obtained by these observers in twenty-four cases of grave infectious diseases were recently communicated to the Société de thérapeutique in a thesis by Jean Azam, according to an abstract from the *Journal de médecine et de chirurgie pratiques* in *The Practitioner* for March, 1908. In enteric fever, particularly, the therapeutic effect has been most evident; eight cases were treated, and they all recovered. Six of the patients were not bled, and among them nine he noted two cases of ascending pyæmia. In one pyæmia gave room for a glaucoma progressus and in

the other a miscarriage occurred at the outset of her enteric disease, to be followed later by a puerperal infection, associated with her typhoid infection. In both these cases the hypophysial treatment was followed by an almost simultaneous rise in the arterial tension; from 12 to 14 the tension rose by degrees to 20. The pulse, which in several patients was as high as 130 to 140, fell gradually to 90 and 84. The temperature, in both these cases, fell from one to two degrees, but went up again when the hypophysial treatment was stopped. Diuresis was well marked in all the patients; in some the quantity of urine was three to four litres. In all the cases convalescence was very quick. In all eight cases the diagnosis of enteric was confirmed by the serum test. In pneumonia the effect was less favorable, but the cases were of extreme gravity. Pituitary gland substance was given in influenzal pulmonary congestion, cerebrospinal meningitis, etc. In all there were four deaths in the twenty-four cases. The daily dose given was  $4\frac{1}{2}$  to 6 grains of the powdered hypophysis of bullock. At the end of his thesis Azam gives a résumé of the effects of hypophysial inadequacy, and the influence of hypophysial opotherapy. Inadequacy is characterized in toxine infectious diseases by (1) a fall in arterial tension, (2) quickening of the pulse. To these two principal symptoms are added secondary effects, including insomnia, loss of appetite, frequent sweat, and painful heat flushes. Under the influence of hypophysial opotherapy in toxine infections are to be noted: (1) Increase of arterial tension, (2) decrease in the rate of the pulse with increase in the force and amplitude of the beats, (3) increased diuresis, (4) increase of weight, (5) suppression of the secondary symptoms of hypophysial inadequacy, (6) a favorable influence on convalescence. It is conceivable that this form of opotherapy will be able to rank beside specific treatment of toxine infections when the quickness of the pulse and the low tension suggest a functional insufficiency, or an actual lesion of the hypophysis.

**Erythema Annulare.**—The subjective symptoms of erythema annulare are said to respond quickly to the following treatment recommended by Cocks (*Medical Record*, March 28, 1908):

R Sodium salicylate, ..... 5v;  
Rhubarb and soda mixture, ..... 3iii.

M. Sig.: 5i in a wineglassful of water every three hours.

The objective symptoms are relieved by the application of the following lotion:

R Powdered calomel, ..... 5ii;  
Zinc oxide, ..... 3ii;  
Carbolic acid, ..... 3xxx;  
Rose water, ..... 3iv.

M.

**Equisetum Arvense in Suppression of the Urine.**—This plant, popularly known as horsetail, and which was at one time reputed to have diuretic properties, has again come into use in the treatment of suppression of the urine where the ordinary therapeutic methods have proved ineffective. Breitenstein (*Correspondenz-Blatt für Schweizer Aerzte*) cites the case of a patient suffering from heart disease and extensive oedema, who, after taking six ounces of a concentrated decoction of equisetum twice daily for six weeks, was quite cured of all

swelling, the urine being raised from 53 ounces to 165 ounces daily (*sic*) by the simple and old fashioned treatment. An infusion of the dry powdered plant, obtained by infusing a tablespoonful of the powdered herb in a cupful of boiling water, and decanting after fifteen minutes, has been recommended as an internal remedy for various hæmorrhages, such as epistaxis, hæmoptysis, menorrhagia, metrorrhagia, and bleeding hæmorrhoids. The dose is a cupful, repeated, if necessary, twice or thrice daily.

**Mistura Ferri Acida.**—In the *Journal of the American Medical Association*, for March 28th, F. A. Faught comments on the various formulas that have been published for the combination bearing the name, *Mistura ferri acida*. He gives the formula employed at the Philadelphia Polyclinic during the time he served there as follows:

R Iron sulphate, ..... gr. xxxvi;  
Magnesium sulphate, ..... 5ii;  
Diluted sulphuric acid, ..... 5ii;  
Compound infusion of gentian, ..... 3vi.

M. Sig.: A tablespoonful in water before breakfast, or two tablespoonfuls in water after each meal.

**Spray in Asthmatic Attacks.**—The following spray is recommended in *Journal de médecine de Paris* for February 22, 1908, for the alleviation of the distress accompanying the paroxysm in asthma:

R Cocaine nitrite, ..... gr. xv;  
Atropine nitrite, ..... gr. viiss;  
Glycerin, ..... 3i;  
Water, ..... ad 5iii.

M.

The spray is applied on the approach of the attack and repeated one half hour or an hour after it. In severe cases the spray is applied night and morning.

**Treatment of Scabies or Pediculosis.**—Babies and adults affected with scabies or pediculosis should, says Cocks (*Medical Record*, March 28, 1908), be washed in warm water, to which borax and tincture of green soap have been added, and allowed to soak for half an hour. After drying a two per cent. ointment of ammoniated mercury applied night and morning for a week will effect a cure.

**Lactic Acid for Alopecia.**—Lactic acid is said by *The Prescriber* to have a specific action in alopecia areata. The following prescription has been given, according to the authority cited, in a number of cases with complete success:

R Lactic acid, ..... 5ii;  
Castor oil, ..... 3ii;  
Alcohol (60 per cent.), ..... ad 5iv.

M. Sig.: To be painted on the patches night and morning.

**Ointment for Tinea Tonsurans.**—In a note on the cure of tinea tonsurans by Cocks (*Medical Record*, March 28, 1908), it is remarked that long and persistent treatment is necessary. The patient should wear a muslin night cap and be isolated. The hair is to be clipped, thirty or more hairs to be epilated daily, and the following ointment rubbed in with a stencil brush twice a day:

R Ointment of red mercuric oxide, ..... 3iss;  
Sulphur ointment, ..... 3ii;  
Ointment of rose water, ..... 5i.

M.

office or express money order payable to the A. R. Elliott Pub-  
lishing Co., or by registered mail, as the publishers are not  
responsible for money sent by unregistered mail.

Entered at the Post Office at New York and admitted for  
transportation through the mail as second class matter.

NEW YORK, SATURDAY, APRIL 4, 1908

## PREVENTIVE MEDICINE AND THE GOVERNMENT.

Two bills affecting the Public Health and Marine Hospital Service have been introduced into Congress, and their enactment would inaugurate a very important movement in the interest of preventive medicine in this country. The functions of this service have been enlarged so often, in response to the growing demand for more active participation by the government in the prevention of disease, that it is necessary from time to time to provide by legislation the authority and facilities required by the service to meet its new responsibilities. The bill entitled "A bill to further protect the public health, and imposing additional duties upon the Public Health and Marine Hospital Service" (H. R. 18792, S. 6101) does this, but, in addition, it provides for the broadest investigation by the service into the prevalence, the conditions influencing the spread, and methods for the prevention and suppression of "tuberculosis, typhoid fever, rabies, and other diseases affecting man."

This bill, if it becomes a law, will mark the beginning of aggressive action by the government in the prevention of those diseases which cause the greatest waste of life, and in entrusting the first organized campaign to the Public Health and Marine Hospital Service, assurance is given that Congress has been aroused to the necessity of assuming, within its constitutional limits, its important share in the warfare against disease. Besides pro-

viding for the investigation of the preventable diseases, the bill authorizes the widespread dissemination, by means of bulletins, exhibits, and reports, of the results obtained as well as of practical information as to the control of infectious diseases. Provision is made for the establishment of a school of hygiene under the administration of the Public Health and Marine Hospital Service, in which instruction may be received by accredited health officers of States, counties, and municipalities, and for the detail of commissioned officers of the service, upon request of the proper health authorities, to cooperate in the sanitary work of States and territories. In accordance with recommendations made by Surgeon General Wyman in his last annual report, certain additional administrative officers are provided for in the bill. These include an assistant surgeon general, to have charge of a new division (that of water supplies and sewerage), a sanitary engineer of high attainments, and a solicitor conversant with general and local laws and regulations relating to the public health.

The growth of the Public Health and Marine Hospital Service illustrates the beneficial effect of rewarding the efficient performance of one task by the imposition of a more difficult one. From the professional and administrative success with which the marine hospitals were conducted, and the familiarity with quarantinable diseases which the care of sick seamen involved, came the administration by the Marine Hospital Service of the national maritime quarantine and the control of the early yellow fever epidemics of the south. The confidence inspired by the devotion and ability of the officers of the service in the performance of these duties resulted in the assignment of new tasks, one by one, until the activities of the service now include the control of epidemics too serious for the resources of local health authorities or which threaten interstate communication (examples fresh in the public memory being the epidemics of yellow fever in New Orleans and of bubonic plague in San Francisco), the administration of the Federal quarantine system, not only in the United States and its possessions, but in every infected port in the world, the investigation of diseases of peculiar local interest, like that of leprosy in Hawaii and of the hook worm disease in the south, the supervision of the production of vaccines and curative serums, the medical inspection of immigrants, and the operation of the marine hospitals.

In the performance of these diversified duties, the Public Health and Marine Hospital Service has been engaged in public health work of the widest scope, and with its well organized and disciplined corps of trained officers, is fully equipped to take

up the new obligations which the bill before Congress imposes upon it. The place in the public confidence which this service holds was well expressed recently by Dr. L. L. Seaman, who said: "I have seen these zealous guardians of the public health in almost every port with which we have commercial relations, always watchful lest contagious or infectious diseases might elude them and fasten upon our native land, and with a fairly liberal personal experience and knowledge of our government in its various departments at home and abroad, I assert that the United States Public Health and Marine Hospital Service is the one department of which Americans have most reason to feel justly proud."

The other bill affecting this service (H. R. 18794, S. 6102) makes belated provision for pay, allowances, and retirement in conformity to that enjoyed by the medical officers of the army. If the same pay, allowances, and opportunities for advancement which exist in the other medical services of the government are not provided, it will be difficult, if not impossible, to attract to the Public Health and Marine Hospital Service young physicians of the type needed as commissioned officers or to obtain men with the training and ability needed to carry on the highly specialized work of some of the divisions in the Hygienic Laboratory. An efficient and contented personnel, satisfied to devote their lives to the work of the service and trained to the highest degree of usefulness, is the factor absolutely essential for the successful performance of the future work of this service.

The course of these two bills through Congress will be followed with interest by all those who have at heart the development of preventive medicine in this country, and their enactment will go far toward removing the stigma that this government does more for the preservation of swine and cattle than for the protection of human life.

#### THE MOTHER OF MODERN NURSING.

If Hippocrates was the father of medicine—and it is customary so to designate him—surely Miss Florence Nightingale may justly be called the mother of such nursing as has now, over practically the whole civilized world, happily supplanted the old style of nursing, almost always worthless and often truly abominable. The nurses' training school of to-day is her creation. Probably it would have come eventually in any case, but it was her marvelous career in the Crimean war, backed by the conscience of the British people, that endowed her with the prestige required to carry out her lofty purposes in the face of foolish and fussy officialdom.

Miss Nightingale's extraordinary services to man-

kind have met with universal acknowledgment, but it is well that in her declining years she has received such a tangible and distinguished token of the fact as the freedom of the city of London, "one of whose most graceful functions it is," says the *Lancet*, "to act as a mouthpiece for the nation in honoring those who have deserved well of their fellow countrymen." The ceremony took place on Monday, March 16th. It is quite in keeping with Miss Nightingale's higher regard for the general welfare than for her own gratification that she should have declined the offer of "a golden casket to inclose the address presented to her, choosing rather," says our contemporary, "that the money thus saved should be spent on some work of charity."

The Crimean war occurred many years back, more than half a century, and Tennyson, who gave the world the other good thing that came out of it, *The Charge of the Light Brigade*, has been several years at rest. It was high time, therefore, that the crowning reward of Miss Nightingale's lifelong labors should come. The prolongation of her most useful life for many years yet is heartily desired for her by public spirited people all over the world, and we are all glad to believe that her memory will be imperishable.

#### OUR PRESENT KNOWLEDGE OF CANCER.

Dr. James Ewing, of New York, [delivered, on November 16, 1907, a very interesting lecture before the Harvey Society, at the New York Academy of Medicine, which lecture has now appeared in print in the *Archives of Internal Medicine*, i, No. 2. In this lecture the author gives a very good synopsis of the cancer question as it presents itself to-day. He states that our knowledge of cancer must be reviewed from three points: The parasitic theory, the theory of cell autonomy, and the modern biological and biochemical study of tumors.

"The search for the cancer parasite has been a chaotic chapter in medical research." It was only natural, remarks the author, that, after the discovery of specific agents in many infections, especially in infectious gummata, researches for a specific cancer parasite should be instituted. But at the present day it cannot be said that these researches have been successful. Although certain irritants and parasites may be effective in producing tumors, no specific parasite has so far been discovered.

In reviewing the theory of cell autonomy Dr. Ewing thinks that it seems to explain sufficiently the enormous and quick growth of tumors. Normally, the organization controls the growth of tissue

cells, the regenerative powers of which are greatly in excess of ordinary needs, so that if called upon the cells may meet extraordinary requirements; if, therefore, the proper external condition or stimulus should arise, the cells will exhibit a phenomenal grade of proliferation. But can such a stimulus be the result of a parasite, not necessarily a specific parasite? Dr. Ewing answers this question by saying that when the theory of a stimulus is accepted, the existence of such a parasite, and even of a specific parasite, must be admitted. But he shows that, to make this theory acceptable, the parasite must invade minute groups of cells in protected organs, even in the embryo of an immune parent, infecting an embryonal cell, but not attacking its immediate neighbor, lying dormant for years and awaking suddenly, doing its destructive work in a very short time.

The third theory is of very recent date. In a biochemical sense, efforts to demonstrate specific qualities in tumor cells have not been very successful. The experiments made show that tumors grow readily in young dogs, rats, and mice, although such tumors seldom or never develop spontaneously in these young animals. From these experiments the theory of cell autonomy becomes important.

Dr. Ewing thinks that in the clinical observation of the general and local conditions of the early stages of cancer, such as can be made only by the physician, lies the chief hope for the present generation of a reduction in the mortality from cancer.

#### DRIED SPUTUM AND THE SPREAD OF CONSUMPTION.

At a recent meeting of the National Society of Medicine, held in Lyons (*Presse médicale*, February 29th), M. Cadéac made some remarks in which he reminded his hearers that he had been one of the first to deny that tuberculous disease was contracted by inhalation, his experiments and communications concerning the matter dating back to 1887 and 1888. He had now made additional experiments tending to show that the disease was not usually spread by dried tuberculous sputum, even by absorption from the alimentary canal. He had mixed dried sputa, taken indiscriminately from all the special receptacles in a hospital service, with the food given to guinea pigs. It was only in very rare instances that the animals had become tuberculous, and then only after they had been made to ingest enormous quantities of the dried sputum. These experiments, he said, were all the more valuable when they were considered in connection with the fact that, to infect a guinea pig with tuberculous disease, it sufficed to

touch the tip of its tongue with a stirring rod dipped in a ten per cent. solution of fresh tuberculous sputum. If the author's experiments are confirmed, and if, at the same time, as is plainly the tendency, we come to regard infection by the digestive canal as more common than infection by inhalation, we shall have to lay much less stress than we do at present on the danger of inhaling tuberculous dust. However, it will be well to pause before acting on such a deduction.

#### A NEW STATE HOSPITAL.

The members of the medical profession in the city of New York have long been convinced that the only temporary solution of the problem of overcrowding in the hospitals for the insane in New York State could be reached by the erection of a new hospital in the southeastern part of the State. It is a matter for congratulation that a bill was introduced into both houses of the legislature last week to provide \$119,250 for the purchase of a site in Rockland County upon which a new hospital for the insane is speedily to be erected. The tract selected by the State Commission in Lunacy comprises 408 acres, and is situated at Congers, on the West Shore Railroad. Almost all desirable features are found in this site, and the price is low if one considers the certain appreciation of values for land within twenty-nine miles of New York, now that the tunnel under the Hudson River to Hoboken has been completed.

The overcrowding of the State hospitals is due almost entirely to the large increase of the insane population in New York city. From Manhattan, Kings Park, and Central Islip State hospitals transfers have been made to all the ten other hospitals in the State, except those of Buffalo and Long Island. In fact, none of the hospitals of the districts in the northern part of the State, with the exception of Buffalo and Utica, would be filled were it not for these transfers. The certified capacity of the thirteen institutions is much overstated at 23,525. The number of patients actually housed in these hospitals has reached nearly 26,000. The only solution of this problem lies in the speedy erection of a new hospital in this part of the State. The question of other hospitals at different points is entirely independent of this prime consideration and secondary to it. It is without doubt a fact that a much larger proportion of our insane population can be cured or can be rendered at least partially self supporting when the great overcrowding now existing is at an end and more individual care and attention is rendered possible. This can best be done by the erection of small hospital groups rather than by putting

up buildings so enormous that no one head can carry the necessary details of administration and medical care.

## AN ANNUAL OF PARASITOLOGY.

We learn that a new annual, to be called *Parasitology*, is soon to make its appearance as a supplement to the *Journal of Hygiene*. Dr. George H. F. Nuttall, F. R. S., is to be the chief editor. It is announced that each volume will contain 400 or 500 pages of text, together with the necessary plates for elucidating contemporary studies of the structure and life history of the pathogenic organism and of the intermediate host or hosts in the case of such diseases as are carried from one vertebrate animal to another by mosquitoes, biting flies, ticks, etc. The new periodical is to be issued by the Cambridge University Press, which has a representative, Mr. C. F. Clay, in Fetter Lane, London, E. C.

## News Items.

**The Second International Conference on the Sleeping Sickness** met at the Foreign Office, London, during the week of March 9th. Lord Fitzmaurice presided and delegates from seven countries were present at the conference.

**The Pathological Society of Philadelphia** will hold its annual conversational meeting on Thursday evening, April 22d. Dr. Richard M. Pearce will deliver an address on the Theory of Chemical Correlation as Applied to the Pathology of the Kidney.

**The Dorchester, Mass., Medical Society** was organized on March 25th, with the following officers for the first year: President, Dr. Madison T. Thurber; vice president, Dr. Robert M. Merrick; secretary and treasurer, Dr. H. F. R. Watts.

**Emergency Hospital, Washington, D. C.**—The resignation of Dr. Charles S. White as superintendent of the institution has been accepted by the board of directors, to take effect on April 15th. He will be succeeded by Dr. E. P. Magruder, of Washington.

**A Gift to the Maine General Hospital.**—It is reported that Mr. William Deering, of Evanston, Ill., has made an unconditional gift of \$25,000 to the Maine General Hospital, Portland. In doing so he anticipated a clause in his will bequeathing that amount to the institution.

**The Harvey Society Lectures.**—The next lecture in the course will be delivered on Saturday evening, April 18th, at the New York Academy of Medicine, by Professor A. E. Taylor, of the University of California, on The Role of Reversed Ferment Reactions in Metabolism.

**Medical and Surgical Society of the District of Columbia.**—At a meeting of this society, which was held in Washington, D. C., on Thursday, March 10th, Dr. F. A. King read a paper on The Pleasures and Advantages of Functional Reversion to Antecedent Conditions of Life, and Dr. Joseph Taber Johnson read a paper on Abdominal Surgery.

**Arkansas Medical Society.**—The annual meeting of this society will be held in Little Rock, Ark., on May 13th, 14th, and 15th. The chairman and the secretary of the Section in the Practice of Medicine are preparing a programme which promises to be one of especial interest, and every effort is being made to make the meeting a success in every way.

**The Army Medical Reorganization Bill.**—This bill, with its amendments, has been passed by the House of Representatives, but the Senate failed to agree with the

amendments of the House, consequently the bill is now in conference. A compromise will probably be arrived at between the Senate and the House, and the bill, as finally modified, will then become law.

**Baltimore Medical Society.**—The semiannual meeting of this society will be held on Tuesday, April 7th. The general subject for discussion will be Expert Testimony, which will be considered from both the medical and the legal points of view. Among those who will take part in the discussion are Dr. George J. Preston, Dr. N. G. Keirle, and Dr. Joseph C. Bloodgood.

**American Society of Sanitary and Moral Prophylaxis.**—A regular meeting of this society will be held at the New York Academy of Medicine on Thursday evening, April 9th, at 8:30 o'clock, under the auspices of the Committee on Education. The following papers will be read: The Ætiology, Prophylaxis, and Treatment of the Social Ill, by Dr. S. Adolphus Knopf; Prostitution in New York City, by Frank Moss, Esq.

**Elmira, N. Y., Academy of Medicine.**—The regular meeting of this academy was held on Wednesday evening, April 1st. Papers were read as follows: Dr. H. R. Ainsworth, of Addison, N. Y., Measles and Its Quarantine; Dr. Anna Stuart, of Elmira, N. Y., Carcinoma of the Breast; Dr. Abraham Lande, of Elmira, N. Y., Cardiac Insomnia. Dr. Ross G. Loop is the president of the academy, and Frank L. Christian is the secretary.

**The Rockaway Tuberculosis Hospital.**—Plans have been prepared for the seaside hospital and sanitarium for tuberculosis patients which is to be built in Rockaway, Long Island, by the New York Association for Improving the Condition of the Poor. The association has raised \$250,000 for the purpose, one half of this amount having been contributed by Mr. John D. Rockefeller. The city has furnished the site. According to the plans the hospital will accommodate two hundred patients.

**A Department of Public Health in Canada.**—Dr. Judson B. Black, member of Parliament for Hants, Nova Scotia, has proposed a resolution in the Canadian House of Commons asking the government to establish a Department of Public Health, whereby all matters relating to public health will be under one responsible head, instead of being scattered through several departments, as is the case at present. All the medical men in the house spoke strongly in favor of the resolution.

**Vital Statistics of Minneapolis.**—During the month of February, 1908, there were reported to the Department of Health of Minneapolis, Minn., 260 deaths from all causes, corresponding to an annual mortality rate of 9.80 in 1,000 of population. Of the total number of deaths, 55 were from pneumonia, 29 from pulmonary tuberculosis, 21 from Bright's disease, and 10 from cancer. There were 2 suicides, and 7 deaths from accidents. There were 194 marriages and 436 births registered during the month.

**The Anglo-American Society of Vienna** is the name of a society recently organized, with headquarters at the Imperial Hotel, Vienna. The object of the organization is to facilitate the visits of English and American students in Vienna, and to make known in England and the United States the artistic and scientific resources of the place. H. H. Princess M. A. Lubomirska is the president of the society, Dr. G. de Griez is the honorary secretary, and Mr. O. S. Phillips, the English vice consul, is the treasurer.

**The Health of Pittsburgh.**—The following cases of transmissible diseases were reported to the Bureau of Health of Pittsburgh for the week ending March 14, 1908: Chickenpox, 4 cases, 0 deaths; typhoid fever, 25 cases, 6 deaths; scarlet fever, 12 cases, 2 deaths; diphtheria, 9 cases, 2 deaths; measles, 229 cases, 11 deaths; whooping cough, 13 cases, 3 deaths; pulmonary tuberculosis, 32 cases, 16 deaths. The total deaths for the week numbered 181, in an estimated population of 403,300, corresponding to an annual death rate of 23.33 in 1,000 of population.

**The Health of Philadelphia.**—During the week ending March 14, 1908, the following cases of transmissible diseases were reported to the Bureau of Health: Typhoid fever, 97 cases, 17 deaths; scarlet fever, 86 cases, 6 deaths; chickenpox, 39 cases, 0 deaths; diphtheria, 72 cases, 7 deaths; cerebrospinal meningitis, 2 cases, 0 deaths; measles, 222 cases, 5 deaths; whooping cough, 17 cases, 2 deaths; pulmonary tuberculosis, 95 cases, 21 deaths; pneumonia, 73 cases, 60 deaths; erysipelas, 7 cases, 1 death; puerperal

fever, 2 cases, 5 deaths; cancer, 15 cases, 21 deaths; tetanus, 2 cases, 1 death; mumps, 29 cases, 0 deaths. The following deaths were reported from other transmissible diseases: Tuberculosis other than tuberculosis of the lungs, 9; diarrhoea and enteritis, under two years of age, 11. The total deaths numbered 527, in an estimated population of 1,532,738, corresponding to an annual death rate of 17.81 in 1,000 of population. The total infant mortality was 118; under one year of age, 88; between one and two years of age, 30. There were 34 stillbirths, 16 males, 18 females.

**University of Pennsylvania Alumni Election.**—The Philadelphia Alumni Society of the Medical Department of the University of Pennsylvania held its annual meeting on March 21st and elected the following officers: President, Dr. J. Allison Scott; honorary vice president, Provost C. C. Harrison; vice presidents Dr. Richard C. Norris, Dr. Howard Sipple, and Dr. De Forest Willard; treasurer, Dr. H. B. Carpenter; secretaries, Dr. B. F. Stall and Dr. William S. Ray; executive committee, Dr. Louis Adler, Dr. C. F. Franklin, Dr. David Parrish, Dr. George B. Wood, and Dr. Louis Saladi.

**Women Physicians in Japan.**—The Japanese medical law recognizes the existence of women physicians, but there is no medical school for women in Japan, and the schools which admit female students are not recognized by the medical law. The establishment of a medical technical school for women has been proposed, but the authorities are not in favor of the suggestion, and think it preferable to create departments for women in two or three of the leading medical schools. Regulations to that effect are being drawn up and will be submitted to the conference of medical technical schools.

**Scientific Society Meetings in Philadelphia for the Week Ending April 11, 1908.**—*Monday, April 6th.* Philadelphia Academy of Surgery; Biological and Microscopical Section, Academy of Natural Sciences; West Philadelphia Medical Association; Northwestern Medical Society. *Tuesday, April 7th.* Academy of Natural Sciences; Philadelphia Medical Examiners' Association. *Wednesday, April 8th.* Philadelphia County Medical Society. *Thursday, April 9th.* Pathological Society; Section Meeting, Franklin Institute. *Friday, April 10th.* West Branch, Philadelphia County Medical Society; Northern Medical Association.

**The Mortality of Chicago.**—During the week ending March 21, 1908, there were reported to the Department of Health 623 deaths from all causes, 335 males and 288 females. The annual death rate in 1,000 of population was 15.00, in an estimated population of 2,107,620. The principal causes of death were: Apoplexy, 5; Bright's disease, 32; bronchitis, 31; consumption, 72; cancer, 26; convulsions, 5; diphtheria, 5; heart diseases, 50; influenza, 9; intestinal diseases, acute, 38; measles, 5; nervous diseases, 23; pneumonia, 111; scarlet fever, 5; suicide, 12; typhoid fever, 6; violence, other than suicide, 24; whooping cough, 2; all other causes, 162.

**College of Physicians of Philadelphia.**—At a meeting held Wednesday evening, April 1st, papers were read as follows: Dr. George W. Norris, Cardiac Arrhythmia from a Practical Standpoint in the Light of Recent Investigations; Dr. William R. Nicholson and Dr. Joseph S. Evans, The Bacteriology of the Puerperal Uterus; Dr. Jay F. Schamberg, The Applicability of the Lumière Process of Color Photography in Medicine; Dr. Milton B. Hartzell, Photomicrographs and Pathological Diagrams of the Skin Obtained by the Lumière Process of Color Photography. Dr. Schamberg also gave a demonstration of color photography with the Lumière process.

#### Infectious Diseases in New York:

It is authorized by the Bureau of Records of the Department of Health for the following statement of new cases and deaths reported for the two weeks ending March 28, 1908.

	March 19-28	March 29-April 5
Scarlet fever	108	102
Diphtheria	10	10
Whooping cough	18	10
Measles	10	10
Smallpox	10	10
Typhoid fever	10	10
Cholera	10	10
Other infectious diseases	10	10
<b>Total</b>	<b>166</b>	<b>162</b>

**New York Academy of Medicine.**—At a stated meeting which will be held on Thursday, April 16th, at 8:30 p. m., the general subject for discussion will be exophthalmic goitre. Papers will be read as follows: The Pathological Changes in the Thyroid Gland as related to the Varying Symptoms in Graves's Diseases, Based upon the Pathological Findings in Two Hundred and Seventy-five Cases of Exophthalmic Goitre, by Dr. Louis B. Wilson, of Rochester, Minn.; The Surgical Aspects of Exophthalmic Goitre, by Dr. W. S. Halsted, of Baltimore; The Consideration of Exophthalmic Goitre from the Medical Standpoint, by Dr. Alfred Stengel, of Philadelphia.

**Rochester, N. Y., Academy of Medicine.**—The Section in General Medicine, which includes neurology, psychiatry, materia medica, and therapeutics, held a meeting on Wednesday evening, April 1st. The evening was devoted to a discussion of the subject of pneumonia, and papers were read as follows: The Bacterial Origin of Pneumonia and the Factors Entering into Its Causation, by Dr. John R. Williams; The Blood in Pneumonia, by Dr. Charles O. Boswell; The Treatment of Pneumonia, by Dr. J. R. Culkin; The Specific Treatment of Pneumonia, Nuclein and Serum Therapy, by Dr. C. E. Darrow. Dr. Edward G. Nugent is secretary of the section, and Dr. T. A. O'Hare is the chairman.

**The Medical Association of the Greater City of New York.**—A special meeting of this association will be held on Monday, April 6th, at 8:30 p. m., at the Democratic Club, Long Island City, under the direction of the chairman for the Borough of Queens. The programme which has been prepared for this meeting includes the following papers: Personal Observations in Scarlet Fever, by Dr. Charles G. Kerley; Must the General Practitioner Use the X Ray Method in the Treatment of Fractures? by Dr. Carl Beck; The Differential Diagnosis of Meningococcus Cerebrospinal Meningitis from Other Types of Cerebrospinal Meningitis, by Dr. Henry W. Berg. Dr. Beck's paper will be accompanied by lantern slide demonstrations.

**Vital Statistics of New York City.**—During the week ending March 21, 1908, there were reported to the Department of Health 1,480 deaths from all causes, 544 marriages, 2,509 births, and 170 stillbirths. The annual death rate in 1,000 of population was 17.46, in an estimated population of 4,442,685. In the Borough of Manhattan there were 767 deaths; in the Bronx, 126; in Brooklyn, 491; in Queens, 66; and in Richmond, 30. Of the total number of deaths reported 168 were from pulmonary tuberculosis, 127 from pneumonia, 127 from contagious diseases, 99 from bronchopneumonia, 97 from diarrhoeal diseases, 56 from cancer, 116 from Bright's disease and nephritis, and 138 from organic heart diseases. There were 16 deaths from suicide, 5 from homicide, and 56 from accidents.

**The Obstetrical Society of Philadelphia.**—At a meeting of this society, which was held on Wednesday evening, April 2d, the following programme was presented: Dr. Alice Weld Tallant reported a case of labor complicated by ventrofixation of the uterus, and the following papers on the subject of ectopic gestation were read: Dr. Stephen E. Tracey, Report of a Case Operated upon for Advanced Ectopic Gestation Associated with Fibromyomatous Uteri; Dr. Theodore A. Erck, Report of a Case of Ectopic Gestation Cordual in Type; Dr. Collin Foulkrod, Report in Outline of Two Cases of Ruptured Extrauterine Pregnancy Illustrating one of the Dangers of Expectant Treatment; Dr. John A. McGlinn, Treatment of Ectopic Pregnancy with report of Cases including one of Death from Hemorrhage.

**Personal.**—Dr. Carl E. Seashore, professor of psychology at the Graduate College of the State University of Iowa, has been elected dean of the faculty.

Professor S. E. Chaillé, professor of physiology and comparative anatomy and dean of the medical department of Johns University, New Orleans, has been awarded a retiring pension by the Carnegie foundation.

Dr. S. J. Meltzer, of New York, will deliver a lecture at the Tenth Annual of Medicine on Tuesday, April 7th, on the Nature of Shock.

Mr. Colton A. Battle, president of the firm of Battle & Co., of St. Louis, Mo., died on Monday, March 23d.

Dr. S. A. Knapp's lecture on Tuberculosis, a Disease of the Modern Age, How to Combat It, was in the series of lectures. It has already been translated into twenty-one languages.

**Samaritan Hospital, Philadelphia, Medical Society.**

An interesting programme was presented at a meeting of this society, held on Saturday evening, March 28th, which included the following reports of cases: A Case of Sarcoma of the Choroid, by Dr. Wendell Reber; Glaucoma following Thrombosis of the Central Retinal Vessels, by Dr. Joseph Clothier; Hydrophobia, by Dr. H. C. Groff; Pleurisy followed by Pneumonia and Pulmonary Abscess, by Dr. Paul F. Bremer; Acute Nephritis, by Dr. I. Newton Snively; Some Cases from the Neurological Dispensary, by Dr. S. F. Gilpin; Thirty Cases from the Oponic Clinic, by Dr. Harry A. Duncan and Dr. G. Morton Illman; Mitral Regurgitation, by Dr. Rae S. Dorsett; Preliminary Report on Normal Saline Enterocolitis in Febrile Cases, by Dr. W. H. Pope; Preliminary Report on Blood Pressure Observations During Major Operations, by Dr. Charles S. Barnes. Dr. H. F. Pfeuger read a paper entitled *The Treatment of Whooping Cough*, Dr. Edward B. Finck read a paper entitled *Some Practical Therapeutic Measures in Skin Diseases*, and Dr. D. J. Kennedy read a paper on the Therapeutics of Varicose Ulcers and Eczema Rubrum. The general discussion on the papers and the reports of cases was opened by Dr. Samuel Wolfe.

**Discussion on the Sanitary Aspect of Milk.**—The New York Milk Committee has made arrangements for a series of five meetings to be held in Assembly Hall, 105 East Twenty-second street, New York, for the purpose of discussing the various questions connected with the milk supply. Among those who have been invited to participate in the discussions are representatives of the Department of Health, milk dealers, representatives of railroads bringing milk to New York, the editors of the New York daily newspapers and of agricultural papers published in New York State, representatives of the State Department of Agriculture, physicians, bacteriologists, and other individuals interested in the sanitary aspect of milk. The meetings will be conducted as private conferences and no reporting will be permitted. The general subjects for discussion at these meetings are as follows: Saturday afternoon, April 4th, at 2:30 o'clock, *The Need for Improving New York's Milk Supply*; Saturday afternoon, April 11th, 2:30 o'clock, *Tuberculosis*; Saturday afternoon, April 18th, at 2:30 o'clock, *Methods for Improving the Milk Supply*; Saturday afternoon, April 25th, at 2:30 o'clock, *Pasteurized Milk*; and Saturday evening, April 25th, at 8 o'clock, *Certified Milk and Other Clean Raw Milks*.

**American Gastroenterological Association.**—The eleventh annual meeting of this association will be held in Chicago on June 1st and 2d. The preliminary programme, which has just been received, includes the following papers: President's Address, by Dr. J. P. Sawyer of Cleveland; A New Method of Ascertaining the Permeability of the Pylorus, by Dr. Max Einhorn, of New York; Isochymia, by Dr. F. H. Murdoch, of Pittsburgh; An Explanation of the Motor Activities of the Alimentary Canal in Terms of the Myenteric Reflex, by Dr. Walter B. Cannon, of Boston; The Chemical Coordination Existing Between the Salivary Glands and the Secretion of the Stomach, and the Effect of Splenectomy on the Gastric Secretion, by Dr. J. C. Hemmert, of Baltimore; Cholecystitis, by Dr. H. W. Bettmann, of Cincinnati; Progress in Gastroenterology, by Dr. A. L. Benedict, of Buffalo; The Nervous Influence on the Production of Sugar in the Body, by Dr. J. J. R. MacLeod, of Cleveland; The Behavior of Some Indigestible Carbohydrates in the Alimentary Tract, by Dr. Lafayette B. Mendel, of New Haven, Conn.; A Comparison of the Guaiac and Benzidin Tests for Invisible Hemorrhage in Diseases of the Digestive Organs, by Dr. Franklin W. White, of Boston; Intestinal Sand, by Dr. Jesse S. Myer and Dr. Jerome E. Cook, of St. Louis; Gastric Ulcer, by Dr. William Gerry Morgan, of Washington, D. C.; Pathology of Malignant Growths, by Dr. W. T. Howard, of Cleveland; Gastrimyorrhæa, by Dr. Julius Friedenwald, of Baltimore.

**The Health of the Canal Zone.**—During the month of January, 1908, the following deaths in the Canal Zone, including the cities of Colon and Panama, were recorded: Typhoid fever, 2; æstivoautumnal malaria, 13; clinical malaria, 24; malarial cachexia, 3; hæmoglobinuric fever, 3; amoebic dysentery, 4; clinical dysentery, 6; beriberi, 2; septicæmia, 3; pulmonary tuberculosis, 22; general tuberculosis, 11; cancer, 5; bronchopneumonia, 7; pneumonia, 28; unicarinalis, 1. The total number of deaths from all causes

on the isthmus was 249, in a total population of 112,062, corresponding to an annual death rate of 26.66 in 1,000 of population. The death rate among the employees of the Canal Commission, both black and white, was 12.72 in 1,000 of population; among the whites the death rate was 11.48 in 1,000; among the blacks 13.16 in 1,000. This death rate is much less than that for January, 1907, when it was 13.01 in 1,000 for the whites, and 30.06 in 1,000 for the blacks. The death rate in the cities of Colon and Panama has also been reduced. The best index of the value of the sanitary work of the Commission is in the malaria incidence. In January, 1907, 1,813 cases of malaria were admitted to the hospitals; in January, 1908, only 642 cases were admitted. During the year the number of employees had increased by 12,000, so that the incidence of that disease is really one fifth of what it was in January, 1908. Both yellow fever and bubonic plague are present both north and south of the isthmus; but no case of either has occurred in the Canal Zone during the year. The morbidity among the employees for the month was 332.69 in 1,000 of population.

**Meetings of Sections of the New York Academy of Medicine.**—A meeting of the Section in Dermatology will be held on Tuesday evening, April 7th. After the presentation of cases previously shown, the following new cases will be presented: Results of the Treatment of Pigmented Nævi by Liquid Air (two cases), and Prurigo of Hebra (two cases), by Dr. Trimble; Xanthoma Tuberousum (two cases), and Pityriasis Rubra of Hebra (two cases), by Dr. Howard Fox; Keloid Treated with the X Rays, and Lupus Vulgaris Treated with the X Rays, by Dr. Clark; and a number of miscellaneous cases.

The Section in Pædiatrics will meet on Thursday evening, April 9th, at 8:15 o'clock. After the presentation of patients, Dr. Eli Long will report a case of Status Lymphaticus. The paper of the evening will be read by Dr. A. F. Hess on *The Distribution of Bacteria in Bottled Milk: Its Application to Infant Feeding*.

The Section in Otolaryngology will meet on Friday evening, April 10th, at 8:15 o'clock. Dr. Edmund P. Fowler will exhibit a suction bell ear douche, and the following reports of cases will be presented: Unusually Atypical Case of Sinus Thrombosis, Importance of the Blood Culture in Diagnosis, by Dr. Seymour Oppenheimer; Cases of Mastoiditis in Elderly People with Unusual Conditions, by Dr. H. A. Alderton; Case of Mastoiditis Complicated by Purulent Meningitis, Encephalitis, Phlebitis of Sigmoid Sinus, Jugular Bulb, and Internal Jugular Vein, by Dr. J. F. McKernon; Case of Sinus Thrombosis Following Removal of Granulations from the Middle Ear, Excision of Internal Jugular Vein, by Dr. E. B. Dench.

**Society Meetings for the Coming Week:**

**MONDAY, April 6th.**—German Medical Society of the City of New York; Utica, N. Y., Medical Library Association; Niagara Falls, N. Y., Academy of Medicine; Practitioners' Club, Newark, N. J.; Hartford, Conn., Medical Society.

**TUESDAY, April 7th.**—New York Academy of Medicine (Section in Dermatology); New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Hudson County, N. J., Medical Association (Jersey City); Medical Association of Troy, N. Y., and Vicinity; Hornellsville, N. Y., Medical and Surgical Association (annual); Long Island, N. Y., Medical Society; Bridgeport, Conn., Medical Association.

**WEDNESDAY, April 8th.**—New York Pathological Society; New York Surgical Society; Medical Society of the Borough of the Bronx; Alumni Association of the City Hospital, New York; Brooklyn Medical and Pharmaceutical Association; Medical Society of the County of Richmond, N. Y.

**THURSDAY, April 8th.**—New York Academy of Medicine (Section in Pædiatrics); Brooklyn Pathological Society; Blackwell Medical Society of Rochester, N. Y.; Jenkins Medical Association, Yonkers, N. Y.

**FRIDAY, April 10th.**—New York Academy of Medicine (Section in Otolaryngology); New York Society of Dermatology and Genitourinary Surgery; Eastern Medical Society of the City of New York; Saratoga Springs, N. Y., Medical Society.

**SATURDAY, April 11th.**—Therapeutic Club, New York.

## Pith of Current Literature.

### THE BOSTON MEDICAL AND SURGICAL JOURNAL.

March 20, 1908.

1. Dental Cases as a Factor in the Ætiology of Other Diseases, By LAWRENCE W. BAKER.
2. The People's Disease: How to Prevent It, By WILLIAM R. WOODBURY.
3. Idiopathic Dilatation of the Colon, with Report of a Case in a Man of Fifty-six, By EMIL H. STONE.
4. Notes on X Light, By WILLIAM ROLLINS.

1, 2. **Dental Caries.**—Baker reminds us that diseased teeth are a cause of other diseases of the human body, and that the control of these dental diseases is a factor in preventive medicine, worthy of attention. Citing authorities on this question and illustrating it by cases, the author concludes that dental caries is the most prevalent disease that attacks man, and is a preeminent factor in the causation of other diseases in the human body. This initial disease is the cause of great physical suffering, to check which many millions of dollars are annually spent in this country. Thus, to prevent dental caries would be a great financial saving and a very great step in preventive medicine. Since this disease is a problem of the civilized world, it should be further investigated; and to aid investigation money should be provided to secure the most eminent men in research work. In the present state of scientific knowledge, the most adequate means of combating dental caries and oral sepsis is by the enforcement of hygienic measures. In order to make his hygienic fight successful, the physician and the surgeon should cooperate with the dental practitioner, for this branch of hygiene requires a thorough knowledge of the teeth and their adjacent tissues. Skilled dentists, therefore, should be placed upon the various hospital staffs to treat this infected area which so materially hinders both surgical and medical treatment. Dentists should give the nurses instruction in the hygienic care of the teeth. Dentists should also be placed upon the staff of medical inspection of the public schools, for the condition of the child's mouth is just as important to its health as the condition of its throat and nose.—Dr. Woodbury is in favor of a movement which would create in Boston an organization that would help encourage and promote better care of the teeth by: 1. Putting into wider circulation the leaflet on the Care and Use of the Teeth. 2. Furnishing literature on dental hygiene, and information and assistance in promoting the cause. 3. Providing popular exhibitions—charts, photographs, instructions, literature—for settlements, schools, and institutions. 4. Giving practical talks on the care of the teeth, and popular and timely articles to the newspapers, country and city. 5. Providing lists of registered skilled dentists who will work for nominal fees for deserving and worthy persons. 6. Discouraging the sale and use of dental preparations injurious to the teeth.

### THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

March 8, 1908.

1. Importance of Ocular Lesions and Symptoms, By LEWIS J. JONES.
2. Infant Mortality in the Summer Months, Medical Adapted at Venetian for the Reduction and the Results, By S. E. GETTY.

3. Adiposis Dolorosa, By JAMES H. G. SULLIVAN.
4. Epididymitis and Orchitis Complicating Typhoid, By JOHN GILLESPIE BEARDSLEY.
5. Foreign Bodies in the Larynx, By F. E. FRANCHERE.
6. Using the X Ray Without Burning, By ALBERT C. GEYSER; Addendum by BENJAMIN P. RILEY.
7. Treatment of Diffuse Suppurative Peritonitis, By STUART MCGUIRE.
8. Mixed Narcosis, By JAMES T. GWATHMEY.
9. A Suggestive Plan for a Modern General Metropolitan Hospital of Five Hundred Beds, By BAYARD HOLMES.
10. Nerve Bridging. Report of One Successful Case, By ALFRED S. TAYLOR.

2. **Infant Mortality in the Summer Months.**—Getty states that the problem of reducing infant mortality from digestive diseases in cities can be summed up in a few words. Clean milk, properly proportioned, for those infants and young children who cannot be fed on the breast, and intelligent care and feeding by the physicians and parents. To produce these results he suggests the following as the necessary means: 1. Rigid State or municipal inspection of all milk from the producer to the consumer. 2. Milk dispensaries properly to modify clean milk in feeding bottles ready for use. The milk may be pasteurized if it is to be used in the tenements. 3. Campaign of education to instruct both physicians and parents in the art of infant feeding and urge on the officials the necessity and economic value of clean milk. 4. Employment of trained nurses in the summer months to follow up cases of digestive disturbances in infants and to aid physicians in their work. 5. The continued improvement of tenement houses so that the dwellers may have the benefits of proper sanitation and plenty of fresh air and sunlight.

4. **Epididymitis and Orchitis Complicating Typhoid.**—Beardsley observes that epididymitis or orchitis, occurring during typhoid fever or during the convalescence from this disease, are comparatively rare complications, and in the majority of cases are due to infection by Eberth's bacillus. These complications may be caused by other pus producing bacteria, but this is unusual. The conditions may also be caused by phlebitis and thrombosis of the testicular veins, the ætiological factor being the same (*Bacillus typhosus*). These complications may occur during the course of the disease, but they are far more likely to occur during convalescence. Although the lesion, as a rule, is unilateral, it may be bilateral, and it may involve either the epididymis or testicle, or both, and not infrequently the cord as well. Effusion into the tunica vaginalis testis is seen occasionally, and there may be a urethritis with urethral discharge. Localized necrosis and suppuration, with extrusion of the testicular substance, is an uncommon termination, the usual termination being resolution, in a week to ten days.

5. **Foreign Bodies in the Larynx.**—Franchere deducts from his observations that in every case of aphonia search for a foreign body should be instituted. There is great variation in the symptoms and pathological results of foreign bodies in the larynx. A careful report of every such case should be made for the next few years, in order that a more extensive literature on the subject may be built up. The great majority of laryngeal foreign bodies now in use are all adapted for the uses to which they are to be put. Laryngotomy is a safer and more conservative procedure in the hands of a competent

surgeon, in many cases, than bungling attempts on the part of an inexperienced laryngologist to remove a foreign body by way of the mouth with imperfect instruments and technique.

**7. Treatment of Diffuse Suppurative Peritonitis.**—McGuire says that the body of the patient should be elevated to an angle of 50 degrees to permit gravity drainage of the flanks. To accomplish this there are two principles in practice, angulation of the patient and angulation of the bed. The disadvantages of the semi-sitting position are: (1) It makes it difficult for the nurse to place the bedpan properly; (2) it is unnatural and subjects the patient to mental and muscular tension; (3) he will slip down when relaxed by weakness or sleep, so that his body will bend at the costal arch and his abdomen will be on a plane parallel with the surface of the bed. To prevent the tendency to assume this false position some surgeons use axillary straps attached to the shoulder rest; some a double inclined plane to support the legs; and others go so far as to elevate the foot of the bed. None of these methods, however, satisfactorily corrects the trouble. The advantages of elevating the head of the bed are: (1) The mattress may be put at any angle; (2) the patient lies on a flat surface, often unconscious of his position; and (3) he is completely relaxed and easily nursed. The difficulty experienced in managing this position has been to get a simple device for raising or lowering the head of the bed, and to devise a means to prevent the patient from sliding down the incline. The author describes his method. The bed elevator consists of a wooden base and upright piece. There are a number of notches on the side of the upright, into which fits an iron link which supports a block to receive the leg of the bed. The link, when horizontal, slips up or down, but when oblique fits into a notch, just as does the lock of an ordinary needle holder. The bed seat consists of a board which, either bare or padded with a pillow, makes a shelf on which the patient sits. A wooden shaft projects downward and passes through a second board which rests against the footpiece of the bed. In the shaft are a number of holes, and a peg placed in one of them will prevent the shaft from passing through the bottom board, and thus transfer the weight of the patient to the foot of the bed. The advantages of the bed seat over a hammock or swing are its rigidity and consequent sense of security given the patient; the ease with which it can be removed and replaced by the nurse when it is found necessary to do so; and also by the fact that there are no straps or ropes on either side of the patient's head or body to embarrass the nurse or alarm the relatives. Both of the devices described can be made by any carpenter at a cost of a few dollars, and will securely maintain the patient at any angle for any time without discomfort.

**10. Nerve Bridging.**—Taylor thinks that the literature of nerve surgery is not well indexed; case reports give results in very general terms, often because of the difficulty of tracing cases and making systematic examinations over the long periods of time necessary. Much experimental work is still necessary to determine the best technique for the solution of the various problems in nerve surgery. Nerve defects can be bridged. Judging from the

material at hand, *suture à distance* offers the simplest and most successful method. The younger the patient and the better the general condition, the more hopeful is the result. Results come only a long time after operation, and depend for completeness on massage, passive motion, electricity, etc. Probabilities are against the bridging of gaps greater than 4 cm., although a few cases are reported. For defects larger than 4 cm. resection of bone or lateral implantation of nerve ends may be used. Good muscle power with bone deformity in an extremity is much to be preferred to complete or serious paralysis.

#### MEDICAL RECORD.

March 28, 1908.

1. Grave Chorea and Its Relation to Septicæmia.  
By B. SACHS.
2. Theoretic Considerations Relative to Immunization by Means of the Tubercle Bacillus and Its Products.  
By WILLARD J. STONE and E. C. I. MILLER.
3. How Much Gynecology and Abdominal Surgery Should the General Practitioner of Medicine Know?  
By W. A. NEWMAN DORLAND.
4. The Diagnosis and Treatment of the More Common Diseases of the Skin.  
By EDMUND LINDLEY COCKS.
5. A Rational Method of Treatment in Chronic Endometritis.  
By JOSEPH M. RECTOR.
6. Examples of Chronic Productive Inflammations in Early Life.  
By ROLFE FLOYD.

**1. Grave Chorea and Its Relation to Septicæmia.**—Sachs is of the opinion that the search for a single specific organism as the cause of chorea is fruitless, and in view of what has already been discovered, entirely illogical. Some forms of chorea are evidently the expression of an acute general infection. There may be a number of different microbic agents giving rise to this condition, but it seems reasonable to suppose that certain bacteria have a special predilection for the motor neurones, while others exert their baneful influence over the sensory elements of the central and peripheral nervous system. The infection may be due directly to those microorganisms or to a toxine formed by them. The author thinks that the microbic origin of the septicæmic chorea has been established. The study of toxæmia and of general infection looms up big in the future study, not only of chorea, but of syphilis of the general nervous system, in the study of meningitis as well as in the researches now in progress on acute anterior poliomyelitis. The prognosis of septicæmic chorea would seem to be extremely grave, but he is not willing to believe that every such case must necessarily prove fatal. As far as the treatment is concerned, it has been unavailing to the present time. Salicylates, sedatives, hypnotics, and the usual forms of hydropathic treatment have been employed. The good results that have been obtained in other severely toxic and infectious disorders by the use of appropriate antitoxines, leaves us some hope for the future. Meanwhile we must endeavor to eliminate, if possible, toxic products circulating in the body.

**5. A Rational Method of Treatment in Chronic Endometritis.**—Rector places his patient in the dorsal position and the discharging (positive) electrode upon the abdomen, a speculum is inserted in the vagina, with its blades generously separated. This brings into view the cervix and the adjacent

parts. The active (negative) electrode is introduced into the uterus and a constant current of five to fifteen milliamperes turned on. Stronger currents are not to be used, for fear of the soft liquefaction and stricture which may follow its caustic action. The surrounding muscular tissue softens, by reason of abstraction of water from the tissues, bubbles of hydrogen gas will be seen issuing from the os uteri, and a copious watery or mucoid discharge flows readily from about the now loosened electrode. After an application of five to ten minutes the sounds are removed, and the irrigator, which is also an electrode, is inserted in their place. While the current is still passing the cleansing solution is allowed to flow. Upon withdrawal of the irrigator, the canal will be found softened, patulous, and free from discharge. The dilatation will remain a sufficient length of time to allow any additional application to be made to the cavity of either uterus or cervix and without any muscular interference. But the source of supply and class of current must be perfect and absolutely under control, positively free from any interruptions of current, sudden stoppage, or increased milliamperage. The milliamperé meter must register accurately the amount and constancy of the current passing. The wires, binding posts, and electrodes must be properly insulated. The current must not be turned on until the electrode is in position, and must then be raised slowly to the required strength. The current must be slowly reduced before the electrode is removed. These precautions are advised because of the adverse mental effect that any disturbance will have upon the apprehensive patient. If the woman suffers any considerable amount of pain, burning sensation, or sudden electric shock, she will become frightfully nervous and insist upon ending the treatment. In beginning the dilatation, the size of the uterine electrode is selected which will readily pass into the canal without giving any pain; in the same gentle manner and with the same aseptic precautions as one would pass a uterine sound for diagnostic purposes. The electrode, which is best made of copper, and properly insulated, is passed onward until the collar which marks the beginning of the insulation presses against the external os. The length of the exposed electrode is shorter than the canal, as he has found that when the tip of the electrode rests against the fundus of the uterus, the patient often experiences a disagreeable (temporary) attack of painful uterine contractions. As the canal gradually dilates and softens, electrodes of increasing size are used, until the entire canal is sufficiently dilated to admit freely the irrigating electrode. As soon as the irrigator is in proper position and the desired current is passing, the cleansing fluid is allowed to flow and freely wash the active mucous surface. One half to one per cent. solution of the tincture of iodine acts best as such cleansing agent.

## BRITISH MEDICAL JOURNAL

March 14, 1908.

1. The Treatment of Pneumonia. By S. WELLS.
2. The Diagnosis of Organic from Functional Affections of the Nervous System. (Pavia, Italy.) By F. S. R. RUSSELL.
3. Some of the Commoner Symptoms of Cerebellar Abscess. By W. TROTTER.

4. The Colony and Bromide Treatment of Epilepsy. By A. J. McCALLUM.
5. A Case of Hysterical Somnambulism Showing Abnormal Acuity of Vision in the Somnambulistic State. By J. W. RUSSELL.
6. A Case of Merycism. By H. F. L. TAYLOR.

3. **Cerebellar Abscess.**—Trotter's paper is based on the study of two cases of cerebellar abscess recently under his care. Cerebellar abscess may produce (1) general evidences of an infective process, (2) evidences of a lesion in the substance of the brain, spreading with variable rapidity, but as a rule subacutely, (3) evidences of a lesion in the lateral lobe of the cerebellum. 1. General evidences of infection. When the case is seen from the beginning there will practically always be a period of onset, during which the symptoms are those of an acute infective process—chill, high fever, headache, loss of appetite, and wasting. There may be no evidence calling attention to the brain, and occasionally the patient may succumb in this stage without any suspicion of the seat of the disease having been aroused. This septicæmic type is the rarest and most puzzling of the clinical forms under which cerebellar abscess presents itself, and almost always escapes diagnosis. Like other infective processes elsewhere, suppuration in the brain is apt to undergo a spontaneous arrest or quiescence after the acute onset. Thus arises a second important clinical type—the latent abscess. Usually, however, some evidence or other of impairment of function will be present. The clinical behavior of these cases is very similar to that of pneumonia followed by empyema. 2. General cerebral signs. The three familiar signs of increasing intracranial tension are optic neuritis, vomiting, and headache. Of these, optic neuritis is the most significant when it is present, but it is often absent in cases of abscess, so that its absence is of no diagnostic significance. Vomiting is a much more common symptom, so that its complete absence throughout would be distinct evidence against cerebellar abscess. The headache is by far most commonly occipital and practically never lateral, so that the substitution of occipital headache for the lateral headache so common in acute mastoid disease should lead to the suspicion of the development of intracranial suppuration. Giddiness is a sign both of intracranial pressure and of cerebellar disease, but in cerebellar disease objects during the attack seem to always move in a definite direction. Causeless wasting is also suggestive. The mental state is one of the most important of this group of symptoms. All stages of impairment of consciousness, from the slightest to profound coma, may be seen, the latter, however, usually only in very advanced cases or in the very acute fulminating varieties. The earliest change is a very slight dullness—a disappearance of spontaneity. But as long as the patient can respond, the intelligence is quite normal. It is unusual for any true delirium or confusion to develop. 3. Localizing cerebellar signs. This is the most important group of signs, as they may be present in latent cases when the first two groups may be absent. They may be divided into extrinsic signs, due to the involvement of the structures outside the cerebellum, and intrinsic, due to the involvement of the cerebellum itself. Among the signs

tures the involvement of which produce the extrinsic signs are the fifth and sixth cranial nerves, with corresponding changes in the area of the trigeminal and paresis of the external rectus on the same side as the abscess. The latter is the commonest isolated sign of cranial nerve involvement in cerebellar lesions, but its diagnostic value is small, as it is not uncommon in acute mastoiditis. Pressure on the pons and bulb may cause hemiplegic exaggeration of the reflexes, etc. The intrinsic signs or motor effects of a cerebellar abscess may be classified as follows: 1. Ocular signs. Nystagmus, weakness of conjugate movements, skew deviation. 2. Signs affecting the limbs. Incoordination, paresis, hypotonicity. In cerebellar abscess, as in any case of increasing intracranial tension in the posterior fossa, the need for operation is urgent, quite as much so as in perforated gastric ulcer or ruptured spleen.

4. **Epilepsy.**—McCallum holds that epilepsy must be regarded as the result of a disease or the perpetuated sequel of one, a vicious habit of brain having been established. For practical purposes the so called predisposing causes may be ignored. In the writer's experience the only constant factor in infantile convulsions has been the evidence of pain and unrest. Pain and nerve tension seem to so disturb cerebral harmony that there is a furious outburst of energy, giving rise to a display of sensory, vasomotor, and motor function constituting the fit. The fit is so obviously an outcome of cortex function that idiopathic epilepsy is usually regarded as a disease of that area. Add to this the fact that epilepsy lasts for years, is very prevalent, and has been widely studied by pathologists, yet no constant, unvarying condition has been found. The author holds that only two factors are necessary for epilepsy—healthy brain and sufficient stimulation. A healthy brain bursts out into fury owing to its overstimulation by sensory impressions poured into it from one or more varying sensory areas, the pain and tension of teething acting like the electric stimulation of experimental observation. The brain gets teased, less tolerant, almost vicious in its habits, so that it will reply, long after teething has passed away, to other sensory disturbances with an epileptic fit. Epilepsy thus becomes a reflex act in its origin and a cerebral vice in its fuller development and perpetuation. The treatment of epilepsy is to remove the cause where this can be done, and where it cannot, to render it inoperative. Some patients are hopeless—developmental cases, those arising in imbeciles, in the microcephalic, in inoperable tumor cases, and probably the confirmed epileptic. But peripheral, traumatic, emotional, and toxic causes give rise to about sixty to seventy per cent. of all cases in childhood and youth, and are curable if treated early and long enough. Bromide treatment is necessary and curative in these cases. Epilepsy being due to severe, prolonged, or repeated sensory stimulation of the brain, that amount of bromide must be used that is necessary to stop the sensory stimulation. The amount in boys varies from 60 to 130 grains a day. Larger doses interfere with the equilibrium, swallowing, and organic reflexes. The toxic action of potassium salts on the heart is probably a myth; it is the bromide that is harmful. When a cure can be ignored. In the few cases

due to absorption of toxic products from overeating, from unsuitable food, or from constipation, diet is of importance, but for the bulk of the cases diet may be summed up in: Three meals a day, everything fresh, everything limited, and meat not oftener than once a day, three times a week being ample.

## LANCET

March 14, 1908.

1. The Surgery of the Spinal Cord and Its Membranes (Hunterian Lecture, II), By D. S. ARMOUR.
2. The Clinical Symptoms of the Cases of Epidemic Cerebrospinal Meningitis Admitted to Belvidere Fever Hospital, Glasgow, During the Recent Epidemic, Together with a Short History of the Disease in Scotland, By W. DOW.
3. A Remarkable Case of Persistent Ingestion of Needles and Their Removal from Different Parts of the Body, Especially from the Organs of the Abdominal Cavity, by Laparotomy Several Times Repeated, By A. NICOLL.
4. A Study of Five Cases of Appendicostomy, By J. L. STRETTON.
5. Congenital Hypertrophic Stenosis of the Pylorus and Its Medical Treatment, By G. CARPENTER.
6. A Suggestion for Treatment in Delayed Chloroform Poisoning, By A. P. BEDDARD.
7. A Case of Cystic Disease of the Maxillary Antrum, By R. LAKE.
8. Lymphangeioplasty: A New Method for the Relief of the Brawny Arm of Breast Cancer, and for Similar Conditions of Lymphatic Œdema, By W. S. HANDLEY.
9. Portal Obstruction without External Evidences of Portal Caval Anastomosis: Its Prognostic Significance, By G. H. C. LUMSDEN.
10. Note on a Case of Compound Depressed Fracture of the Vault of the Skull: Operation and Recovery, By H. R. BEALE.

1. **Surgery of the Spinal Cord.**—Armour, in his second Hunterian lecture, divides cases of injury to the vertebral column into two main classes—those in which the functions of the spinal cord are not interfered with and those in which there is more or less interference with the functions of the spinal cord, with or without obvious injury to the vertebral column. The questions that arise in discussing the subject of operation in cases of fracture-dislocation of the spinal cord are, in order of importance: 1. Will any benefit to the patient result from the operation? 2. Will his life be endangered by the operation? 3. Will he be made worse as a result of the operation? It is essential, in order that an operation should be perfectly successful: (1) To remove enough laminae to be absolutely sure that there is no remaining pressure on the cord; (2) to remove any projecting bone, whether it be a portion of the vertebral bodies or one or more articular processes; (3) to remove all blood clots, even though laminae of unaffected vertebrae have to be removed to do so; (4) to open the dura mater to ascertain definitely the condition of the cord; and (5) to see that the cord dilates to its full extent again, and that pulsation returns (this is only possible where the cord has not been completely destroyed). The operation may be expected to relieve pressure, or, at any rate, remove any doubt as to whether continued pressure exists. Degeneration as a result of pressure appears within four days. If the spinal cord be not completely destroyed, continued pressure may succeed in completing its destruction. Therefore, operation is indicated (1) to relieve pressure

from depressed or displaced fragments of bone; (2) to relieve pressure from blood clot or from extensive hæmorrhage, either extradural or intradural; (3) to relieve pressure and to prevent further destruction from œdema by enlarging the constricted bony canal; and (4) to remove the future danger of pressure from exudate and inflammatory thickening. No operation will restore a cord in which complete transverse section has taken place. But there are no symptoms by which we can in a reasonable time determine *beyond a doubt* the presence of a complete transverse section of the spinal cord. So that we should feel compelled to give the patient the benefit of an operation which does not endanger his life, but which does lessen his pain.

**6. Delayed Chloroform Poisoning.**—Beddard is inclined to favor Rosenfeld's view as to the nature of delayed chloroform poisoning. He believes that when cells are poisoned by chloroform their metabolism is so altered that whilst they can utilize carbohydrates well they can oxidize proteids but imperfectly and fats even less well. Consequently as soon as the cells have used up their meagre store of carbohydrate, their hungry condition causes a breaking down of tissue proteid and a transfer of fat to them; but since neither of these foodstuffs, and especially the fat, is properly utilized, the cells remain in a condition of severe starvation which may rapidly lead to their death through lack of energy. But if an animal poisoned with chloroform is fed with dextrose, the transfer of fat is prevented because it is no longer necessary, and recovery is much more likely to take place than when the animal is starved. Feeding with carbohydrates does not prevent the poison from damaging the cells, but it does provide the cells with the source of energy which they can most easily utilize, and may prevent their dying from acute inanition and so give them time in which to recover. The writer therefore suggests that patients suffering with delayed chloroform poisoning be fed with dextrose—either by mouth, by continuous rectal infusion, or even by intravenous infusion of a six per cent. solution.

**8. Lymphangioplasty.**—Handley states that among the complications of breast cancer none is more terrible than the brawny swelling of the arm coming on in the later stages of the disease. The pain is so excruciating that amputation has been performed for its relief. It is in all probability due to a destruction of the lymphovascular system of the arm. Bearing this in mind the author, having such a case under his care, introduced into the subcutaneous tissue of the swollen arm a number of buried silk threads, running longitudinally upwards from the wrist to terminate in the loose and healthy areolar tissue in or beyond the axilla, and spaced out at convenient intervals around the limb. The operation was analogous to the drainage of a marshy field by means of buried pipes; for stout silk threads, if not under tension, remain unabsorbed for some years, and the absence of organization and coagulation in their interior insure the retention of their capillary power. The result was immediately beneficial, the swelling going down, the pain disappearing, and the power of motion returning. In another similar case the same results were obtained.

March 7, 1908.

1. The Liver in Diseases of the Kidney. Study of Experimental Lesions.  
By LEON BERNHARD and L. LAEDERICH.
2. Pyocyanasis in Therapeutics.  
By R. ROMME.

**1. The Liver in Diseases of the Kidney.**—Bernhard and Laederich state as the result of a series of experiments that, 1, sudden and absolute suppression of the renal function, by bilateral nephrectomy, ligature of both ureters, or total necrosis of the kidneys, produces in the liver a congestion, usually intense, resulting in an extravasation of blood corpuscles or in the formation of little hæmorrhagic foci, habitually generalized about the vessels, but frequently presenting its maximum of intensity in the centre of the lobule. The intracapillary leucocytosis is very marked. The cellular modifications are various. Some cells have a grumous appearance due to the condensation of the protoplasm. The glycogen has disappeared, and consequently the protoplasmic granulations, larger than usual, are conglomerated and mask the cytoplasmic reticulum. Other cells show vacuolization. These cellular modifications change the appearance of the lobules. 2, Partial suppression of the renal functions by nephrectomy, ligature of one ureter, or by the direct production of a nephritis, produces an entirely different set of changes in the liver. Hypertrophy of the liver is frequent, at times considerable, due to the multiplication of cells. Under the microscope the hepatic cell presents an aspect which the authors have denominated *état clair*, a clear state, which they find to be constant, sometimes generalized in all the cells, sometimes localized in a portion of a lobule. The conclusion from these experiments is that renal insufficiency may induce certain lesions in the liver, and is to be looked upon as the true cause of complex lesions of that organ which are to be observed following renal disease in man.

## BERLINER KLINISCHE WOCHENSCHRIFT.

March 2, 1908.

1. A Skeleton of the Thorax for the Purpose of Demonstration of the Position of the Levels of the Valves of the Heart.  
By H. VIRCHOW.
2. Concerning an Aneurysm of the Ascending Aorta Fixed in Situ.  
By H. VIRCHOW.
3. Traumatic Appendicitis.  
By ADOLF EBNER.
4. Concerning Gummatous Disease of Both Nuclei Caudati.  
By CAMPBELL.
5. Use of von Pirquet's Method for Diagnosis of Glanders in Man.  
By H. MARTEL.
6. The Question of Myeloid Leuchæmia.  
By THEODORE LEHMANN and ERIC JAK.
7. Concerning the Development of Balneology During the Past Decade.  
By FRANKENHÄSER.
8. The Discussion Concerning the Cellular and Constitutional Typhus Reaction.  
By C. von FRANK.
9. Reply to von Pirquet's Article.  
By A. WERNER.

**1. Position of the Valves of the Heart.**—Virchow says that the pulmonary valve is at the level of the third cartilage, the aortic at the level of the upper border of the fourth cartilage, the mitral at the level of the lower border of the fourth cartilage, and the tricuspid at the level of the end of the fifth

intercostal space at the margin of the sternum. The tricuspid is in the mesial plane, the pulmonary 25 mm. to the left, the aortic almost exactly in the mesial plane, the mitral 37 mm. to the left. The pulmonary is situated 40 mm. from the anterior surface of the thorax (not the skin), the tricuspid 45 mm., the aortic 55 mm., and the mitral 85 mm. These measurements and levels apply to the middle points of each valve mentioned; the measurements and levels of other parts of the valves, as well as of other parts of the heart, such as the septa between the auricles and the ventricles, the Eustachian valve, the opening of the sinus venosus, etc., together with the positions of the various parts, are carefully worked out.

2. **Aneurysm of the Ascending Aorta.**—Virchow describes in minute detail a specimen of aneurysm of the aorta which began at the aortic valves, so as to involve the sinus of Valsalva, and was so extensive that the innominate and left carotid arose from it, while the left subclavian arose from the aorta beyond the aneurysm. At the left end of the aneurysm there was a sharp angle in its lower wall.

3. **Traumatic Appendicitis.**—Ebner reports a case in which symptoms of appendicitis followed a contusion of the abdomen. Operation two months later revealed an abscess cavity containing a fecal concretion which was removed. The author considers that in this case the contusion of the abdomen was the actuating cause of the inflammation of the appendix, to which the latter was predisposed by the presence of the fecal concretion.

4. **Gummatous Disease of Both Nuclei Caudati.**—Campbell describes the case of a man, twenty-two years of age, who came under his observation with a subnormal temperature, a small pulse, 50 to 90 per minute, scarcely to be felt. He lay still in bed, hardly spoke of his own accord, showed no interest in his surroundings, appeared stupid, and had no control over his urine and fecal movements. Finally he was attacked with bronchopneumonia and died. Autopsy showed that both nuclei caudati had been destroyed by gummata. This case shows that lesions of the nuclei caudati do not produce paralysis, affect the reflexes, or the sensation of pain. The other perceptive qualities of the skin could not be ascertained because of the mental condition of the patient, but the impression was given that no disturbance of this kind was present.

5. **Pirquet's Method for Diagnosis of Glanders.**—Martel reports first the case of himself, infected with glanders in 1894, and reaction obtained from mallein applied to cutaneous ulcers, though no reaction was obtained in ten control persons, the skin of whom was scarified and mallein applied. Then follow several other cases during the past year in which mallein has obtained a distinct reaction in cases of glanders, though not in the controls. In one case a positive reaction was obtained by means of mallein through the conjunctiva.

By LANDMANN
16. Obituary of Alphons Laveran,  
By MARTIAL
17. The Swedish Physician,  
By KRAUSS

1. **Behavior of the Heart After Long Continued and Strenuous Wheeling.**—Dietlen and Moritz state as the result of their investigations that they did not find a single case of dilatation of the heart ascribable to this cause, but that the hearts of wheelmen showed a tendency to diminution after an excessive strain, or, in practiced riders, after an unusual and exhausting tour. This tendency differed in degree in different persons, but seemed to be present in all. In many cases this acute diminution did not appear at once, but gradually, after the elapse of hours or days.

4. **Bactericide and Hæmolytic Efficiency of the Material in Leucocytes and Blood Plaques and of Lymph.**—Schneider sums up his conclusions in the following manner: The leucocytes with polymorphic nuclei contain bactericide material, which they can excrete in vitro or during life under the influence of certain stimulations. These "leucins" are not identical with the alexins circulating in the blood. They belong rather as material *sui generis* to the natural antibacterial protection apparatus of the animal organism, together with the alexin of the blood and the phagocytes. The bactericide action of the lymph in inflammatory oedema rests in great part upon extracellular leucocyte material, while the vessel lymph contains alexin. The hæmolytic action of the extract of the lymphatic glands is to be ascribed to other material than that which produces the hæmolytic action of the blood. The blood plaques do not come into consideration as distributors of alexin.

6. **Skin Reaction After Inoculation with Diphtheria Toxine.**—Schick has shown that the human skin reacts to the inoculation of diphtheria toxine; he asserts to have shown that the reaction is specific; he hopes to obtain in this way an exact and rational dosage of the serum to be used, and thus to secure an advance in the treatment of that disease.

7. **Clinical Importance of the Difference Between the Temperatures in the Rectum and Axilla.**—Propping says that the abnormally great difference of temperature between the rectum and

axilla is due to reduced axillary temperature in both healthy and feverish organisms. The difference of temperature is inversely proportional to the heat production in the muscles. The great difference of temperature is present in all febrile diseases; in peritonitis in about one fourth of the cases at the height of the disease. The great difference of temperature is of serious prognostic importance in peritonitis.

**8. Lumière's Color Photography.**—Wilms and Eggenberger describe the method of color photography in detail, including the development and fixation of the negatives.

**9. Cholesterine Exudates in the Pleural Cavity.**—Ruppert reports a case in which cholesterine was present in such quantity in the pleural exudate as to be noteworthy, and attempts an explanation of its presence other than a transformation of the elements of the exudate.

**10. Sarcoma in a Stump.**—Capaldi reports the case of a man, fifty-five years of age, whose forearm was amputated in 1886. In February, 1907, he struck a piece of wood against the stump, and not long afterward a sarcoma appeared in the scar. Capaldi does not think the traumatism was responsible for the appearance of the tumor.

**11. Avulsion of the Mesentery in Abdominal Contusions.**—Autenrieth reports a case of severe contusion of the abdomen in a child, four and a half years old. Laparotomy was performed because of the symptoms of internal hemorrhage, and a very extensive laceration and avulsion of the mesentery was found which necessitated the excision of a considerable portion of the small intestine that had been deprived of its nutrition. The child recovered.

**12. A New Medicine Glass.**—Strübe has devised a rather complicated glass and tube for the administration of medicines without injury to the teeth. It consists of two globular vessels, one large and one small, each with a tube. The tube of the smaller enters that of the larger, so that fluids coming from the two vessels mingle. The medicine is supposed to be put in the smaller vessel, while the larger is filled with some indifferent fluid such as water or milk. The tube is introduced far into the mouth, when the fluid can be drank without appreciation of the bad taste or injury to the teeth.

1. Consumptive Sanatoria: Are They Worth While? By DAVID LAWSON.
2. Case of Injury to the Motor Area of the Brain. By G. BERENDE BOEHMAN.
3. Case of Multiple Exostoses in a Rabbit Subject. By A. VOUG.
4. Operative Procedure in Relation to Disease of the Frontal and Sphenoidal Sinuses. By W. S. SYME.
5. Preliminary Note on Quinine Sulphate as a Factor in the Causation of Blackwater Fever. By D. McCAY.

**1. Consumptive Sanatoria: Are They Worth While?**—Lawson shows, on the basis of statistical material that the fact that eight years after discharge from sanatoria so large a number as seventy-three per cent. of persons treated were still capable of work, and of those over sixty-one per cent. enjoyed full working capacity, must effectively refute

the contention of those who assert that the clinical results of sanatoria do not justify their existence. He then takes up the commercial objection, and cites the city of Glasgow. There is good reason, says our author, for stating that not less than 700 males died of pulmonary consumption in the city of Glasgow in the year 1906. The average age at which these deaths took place was roughly thirty-one years, and, taking the ascertained average wage earning capacity for England and Wales, 30s. per week is a fair average wage earned by those sufferers when in good health. Insurance companies inform us that, dying at thirty-one years, those who then succumb had their life and rate paying term curtailed by twenty years. It is thus merely a matter of arithmetic to ascertain what the mortality from consumption is yearly costing the city of Glasgow in ultimate wage earning capacity. Calculated on this basis, the annual loss amounts to over £1,000,000 sterling. If it pays insurance companies to preserve their clients' lives for the premiums they then continue to pay them when so restored, does it not seem probable that if—with a view to lessening the enormous annual drain upon her resources, in addition to the heavy claims made by that section of survivors who, deprived of their breadwinners, become chargeable to the poor law rates—the corporation of Glasgow were to provide one or more consumptive sanatoria, and maintain them as they do the other infectious fever hospitals out of the rates, their experience would prove here, as it has done elsewhere, that such expenditure is worth while?

  3. A Case of Matricide and Attempted Suicide, with Brief Psychological Analysis. By W. K. WALKER.
  4. General Considerations as to the Nature and Relationships of Hysteria. By R. C. WOODMAN.
- 4. General Considerations as to the Nature and Relationships of Hysteria.**—Woodman remarks that the mechanism of the production of hysteria is better known than that of the other mental disorders. The origin of its salient features in divisions in consciousness has been repeatedly shown. The cause of its more characteristic symptoms is found in thought. Few workers seek its cause in this or that unknown toxine. We can see that it is functional in the same sense that normal thought is functional, and that we have no more reason to look for a poison in the system or a change in the structure of the cells upon some given day, when a patient has become hysterical, than we have to look for them after any other change in opinion or point of view. We believe that some change in the physiological chemistry of the brain occurs with every thought and emotion, just as some change accompanies every movement of a muscle, and the change in hysteria, at the moment of its inception seems purely a mental change. This does not alter the fact that mental stress, whether it be hysterical or not, sets up nutri-

tive disorders, and secondarily extensive changes in the tissues and fluids of the body. With the functional nature of hysteria in mind, it is possible to regard the mental disorders from a new point of view, and to inquire to what extent they may be thinking disorders as well, and functional in the same sense. Our knowledge does not suffice to answer the question raised, but such a query deserves consideration along with the hunt for bacterial poisons and cellular degenerations. Perhaps in this may be found the explanation of the surprising amount of old knowledge and opinion to be had from almost any long standing dementia, if we can by any means temporarily overcome his lethargy, and of the improvement which comes when the patient's interest can be aroused. It seems in part at least as if such patients had merely fallen into bad habits of thought. The recognition of hysteria as a psychosis the author thinks tends to bridge the gap which has been allowed to grow between diseases of the body and diseases of the mind, and to give a wider outlook and a new point of view from which to regard the other insanities. It makes it possible to correlate the insanities with what most physicians in their practice and thought regard as nervous diseases, and through them the physician and the patient's friends can come to some conception of what goes on in the insane person's mind, and of how such insane thoughts can arise and be entertained. It need not be supposed that the hysterical process is the only one through which mental aberrations occur. Rather in the past its rôle has been almost totally overlooked. The studies in hysteria should be applied to the problem of insanity, and the functional element sought in every mental disorder, and its mechanism be made clear if possible, whether it be hysterical or some other as yet unnamed type of reaction. Thus we may hope to attack psychically in a rational way the psychic element of psychic disease.

### Proceedings of Societies.

#### NEW YORK ACADEMY OF MEDICINE.

*Meeting of February 6, 1908.*

The President, Dr. JOHN A. WYETH, in the Chair.

This meeting was held under the auspices of the Section in Obstetrics and Gynecology and was devoted to a review of RECENT ADVANCES IN OBSTETRICS AND GYNÆCOLOGY.

#### The Present Significance of Chorioepithelioma.

—Dr. JAMES EWING said that he was firmly convinced that this group of tumors could be subdivided and different prognoses established on their histological structure. Briefly, the conclusion was reached that chorioepithelioma included three rather distinct tumors, which were distinguished by their gross appearance, histological structure, prognosis, and indications for treatment. Very uncertain and contradictory opinions were at present maintained regarding this. In 1895 Marchand pointed out that there were two types of chorioepithelioma, one typical, the other atypical. Yet, while Marchand had stated that the atypical variety, composed chiefly of giant cells, was comparatively benign, and he and another author had stated that it was a crime to

remove the uterus for this variety, because it was benign, all writers had not agreed as to the position of the atypical chorioepithelioma.

The typical choriomata of Marchand had shown extreme variations in structure and clinical course. While some had proved very malignant, Schlagenhauser in 1899 had pointed out that recovery might follow after (1) spontaneous extrusion of the tumor from the uterus, (2) removal by curetting, (3) partial removal with the knife. Six cases were on record in which recovery had followed where pulmonary metastases were believed to have occurred. On the other hand, some of these tumors were excessively malignant, and Schmauch had said that it was a crime to remove the uterus, because of the bad results following. Here, then, was a tumor with which hard words met the ill advised surgeon who ventured to operate, because it was so benign and because it was so malignant. There were no histological signs by which the different prognoses could be determined. Here was a unique situation in tumor diagnosis, in which there was no relation between histological structure and prognosis. The following classification and nomenclature were suggested:

1. Syncytioma, the atypical chorioma of Marchand. This tumor produced a more or less diffuse infiltration of the myometrium, or there was a large intrauterine tumor, leading to marked enlargement of the uterus, but not tending to perforate the organ and not giving rise to metastases. Histologically the tumor was composed of large syncytial wandering cells in the walls of sinuses and in the musculature. Hæmorrhage, cachexia, suppuration, and perforation by the curette might prove fatal. In the early stages the prognosis was good.

2. Chorioadenoma destruens, malignant placental polyp. This tumor tended to infiltrate the sinuses of the uterus, considerably enlarging the organ, but not splitting it by a compact growth. Metastases occurred in the lungs and vagina, but recovery might follow, certainly after vaginal metastases or after partial removal, possibly after pulmonary metastases. Histologically the growth showed villi.

3. Choriocarcinoma. This tumor was a relatively small, circumscribed growth in the musculature, tending rapidly to perforate the uterus without greatly enlarging it, and to cause local and pulmonary metastases. Histologically villi were absent. Langan's cells and syncytium were present in masses. Morphological signs of anaplasia and malignancy were always marked. The atypical and diffuse growth of cells yielded a structure to which the term carcinoma was commonly applied. Tumors of this structure were probably always fatal. An operation sometimes seemed to accelerate their course. The uterus should be removed as soon as possible. Infraction of the lines laid down in this classification might result in inability to determine the true position of the tumor, from insufficient curettings, the occurrence of intermediate types of tumors, or differences in structure in different portions of the same tumor. Dr. Ewing then illustrated the different types of these tumors by lantern slides.

**Recent Advances in Obstetrics.**—Dr. EDWIN B. CRAGIN said that marked advances had been made along three lines, a better knowledge of obstetric

pathology, a better knowledge of the mechanical problems of delivery, and better procedures. Distinct advances had been made in the toxæmia of pregnancy, as shown in pernicious vomiting on the one hand and eclampsia on the other. In the pernicious vomiting of pregnancy the chief pathological lesion was a fatty and dropsical degeneration of the liver, and, if the condition existed long enough, the lesions were practically identical with those of acute yellow atrophy. There was more or less degeneration of the renal epithelium of the convoluted tubules. The urine contained acetone, diacetic acid, beta oxybutyric acid, indican, and perhaps a trace of albumin and a few casts. These cases, as a rule, showed a high amount of ammonia nitrogen, high amido acid and undetermined nitrogen, and a low urea nitrogen. The hepatic and nephritic types were recognized clinically. In the hepatic type, aside from the convulsions, there was vomiting, with little œdema, little albumin and casts, often jaundice, tenderness over the liver, and ascites. In the nephritic type there were headaches, disturbances of vision, high tension pulse, nervous irritability, marked albuminuria, and casts. These two types were often combined. In the livers studied by Dr. Cragin there were three varieties of lesions. In the nephritic type the cells near the periphery of the liver showed a moderately fatty and dropsical degeneration, without necrosis. In the hepatic type the fatty and dropsical degeneration at the periphery of the lobules was very marked; the cells had lost their nuclei and were in fact necrosed cells. There were necrosis at the centre of the lobule, a zone of fatty and dropsical degeneration near the periphery, and a few normal cells at the periphery along the portal vessels. In the third variety there was an area of degeneration of the liver cells with hæmorrhage, the so called hæmorrhagic hepatitis. The lesion was situated at the periphery of the lobule. In eclampsia the myocardium often showed degeneration, and the brain œdema and hæmorrhage. In the nephritic type of eclampsia two classes of patients were recognized, those who had previously suffered with nephritis, and in whom the eclampsia had developed from an acute exacerbation of the old trouble, and those whose kidneys had been previously free from disease. Figures presented by him showed a marked resemblance between the hepatic type of eclampsia and the pernicious vomiting of pregnancy, i. e., ammonia nitrogen, amido acid, and undetermined nitrogen above normal, and urea nitrogen below normal.

We now had a better knowledge of the mechanical problems of delivery. We recognized earlier the posterior positions of the vertex and anterior rotation of the occiput was performed by the obstetrician relatively early when Nature failed to accomplish this. In pernicious vomiting cases one did not feel that he had done his duty by his patient unless the urine had been examined and the nitrogen partition determined, and the presence or absence of acetone, diacetic acid, beta oxybutyric acid, indican, etc., ascertained. The laboratory findings should be studied in connection with the clinical picture. In pernicious vomiting of pregnancy the best results were obtained by color irrigations, rectal feeding for a short time only, and early emptying of the uterus. Prolonged menorrhagia and metrorrhagia following

labor, abortion, or an operation for hydatidiform mole should be looked on with suspicion, and early diagnosis should be made and early hysterectomy performed in case it was chorioepithelioma, for that operation alone gave hope. The induction of labor two weeks before term would often secure a relatively easy and safe birth for a child which otherwise would be lost. The improved methods of inducing labor at the proper time for a child to pass the given pelvis, and the low mortality of Cæsarean section, had largely reduced the number of cases in which craniotomy was considered justifiable. The operation of pubiotomy was still *sub judice*. A well trained man might repair a lacerated cervix immediately after labor, but a note of warning should be sounded, that the morbidity if not the mortality of the patients was markedly increased, and the old rule for the general practitioner was a good one—immediate trachelorrhaphy for hæmorrhage only.

**Advances in Gynecology.**—Dr. HERMANN J. BOLDT presented a paper on this subject (see page 527).

**The Practical Application of Our Recent Knowledge in Obstetrics.**—Dr. EDWARD REYNOLDS, of Boston, read this paper. The methods of practice which he wished to present were based upon the belief that the mortality of the Cæsarean section varied greatly in accordance with the period of labor at which it was performed; that the mortality of the section late in labor was too great to permit of its performance in the interests of the child alone; that the maternal mortality of the section performed even so early as the end of the first stage of labor was greater than that of an ordinary high forceps operation or version; and that the mortality of the section done at the time of election, in advance of labor or at its very beginning, the primary section, was so low that it was a safer operation for both patients than a difficult high forceps operation or version when performed for mechanical obstacles. His own experience with section now comprised thirty cases without mortality. He divided the operations into three classes: Those done before labor, or the primary; those done early in labor, or the secondary; those done late in labor, or late sections. His completed tables contained 289 cases of operations by twenty different operators; of these, 82 were primary, 158 secondary, and 49 late. The late cases showed a mortality of over twelve per cent.; the secondary cases, four per cent.; the primary cases, slightly over one per cent. He offered the propositions that a section undertaken under every surgical advantage in advance of labor was less dangerous than one performed after even a few hours' endurance of the exhausting physiology of labor, and under the technical conditions incident to such work; that the section, performed after a full test in labor had demonstrated the approaching failure of the natural forces, was an operation favorable to the child, but more dangerous to the mother than the intrapelvic methods of extraction with forceps or by version. There could be no plainer or more obvious deduction than that, when the Cæsarean section was necessary, it was desirable that it should be determined upon in advance, and performed as a primary operation. He ruled out secondary section as an operation of choice. To attain accurate results,

we should estimate with equal care the pelvis, the passenger, and the probable maternal power as a propelling engine. To estimate these in difficult cases, it was usually necessary to see the patient repeatedly during, and when possible before, pregnancy. The whole matter of the size and shape of the pelvis was as yet in its infancy.

In conclusion, he believed that, to avail ourselves of all the resources of our art in the management of difficult labor, we should see the patient at intervals during pregnancy, and, where the circumstances permitted, before pregnancy; in cases where the unfortunate history of previous labors or the existence of evident deformity had brought the question of the safety of labor into consideration before another pregnancy had occurred. Such a detailed observation of pregnancy, and such painstaking investigation of the mechanical conditions, would be manifestly impracticable and unnecessary in the routine practice of midwifery in multiparæ. It was applicable only in cases in which difficulty could be reasonably expected. He believed the general practitioner should be taught how to select the cases in which danger threatened, but might be forestalled by an early and accurate comprehension of the circumstances. All primiparæ ought really to be examined for determination of the mechanical conditions during pregnancy, and this procedure was growing in repute. The following should have a determination of the mechanical conditions during pregnancy: 1, All primiparæ of very small stature. In this type of women the symmetrically small pelvis, the pelvis nana, was to be looked for. 2, All primiparæ who had done heavy muscular work during the period of development, and more especially those who presented a short, squat, short legged appearance. In this class of women the flat pelvis were particularly frequent. 3, All primiparæ with the narrow hip, long, straight legged, flat backed, boyish type of figure. In this type of women we found the true justo minor, or neutral, type of pelvis so frequent. 4, All primiparæ with bandy legs, protuberant buttocks, prominent abdomen, and an unusually hollow lumbar region. These women were often rather wide hip, markedly feminine in figure, and at first suggested favorable labor; but it was in such women that the pelvis with excessive inclination of the brim and exaggerated curvature of the pelvic axis were mostly found. 5, All primiparæ of delicate health. Many of these women had easy labors, but in them even moderate mechanical difficulties assumed importance. 6, Multiparæ who had had even one difficult or disastrous labor. Few men would doubt the wisdom of these propositions when placed before them on paper, but to effect their present adoption in practice was quite another thing.

DR. WILLIAM M. POLK said the ordinary practitioner was not in a position to enter into the niceties of laboratory work. The only way to anticipate a dire calamity was to keep a very close watch upon the women whose uteri had not undergone proper involution. He regretted that Dr. Cragin had failed to tell them of the advantages of a slow forceps delivery. There had never been anything so potent for good as the obstetric forceps, but all realized that, when used with a rush for the purpose of terminating labor quickly, it was capable of causing dan-

ger which was not limited to external passages; but, apart from the dangers of sepsis and lacerations, it was responsible for the great number of sad cases of procidentia. The fact that forceps delivery could be extended over an hour or longer, until such a time as the uterus was coaxed to do its duty, seemed to him to be worthy of earnest consideration. Disorders in young women were very frequently the groundwork of many of the after conditions, such as diseased ovaries, which ultimately led to those wretched cases of neuroses which revolved around ovarian pains. There was an immense number of young women beginning menstruation under conditions which were far from hygienic; this function, carried on under conditions of ignorance as to its true significance and true pathological conditions, laid the foundation in girlhood of subsequent ailments. Time and time again the treatment of simply removing adenoids that grew in the uterus had been sufficient, not only to relieve the condition of the sexual organs, but to improve the condition of the patient. He also wished to emphasize the vast advantage of early and prompt incision and drainage by the cul-de-sac in those cases of pelvic peritonitis associated with septic infection of the uterus.

Dr. J. CLIFTON EDGAR agreed with Dr. Cragin in the main as to the statements made about the toxæmias of pregnancy, and he was grateful to him for bringing out the value of the nitrogen ratios as diagnostic factors. He believed that to-day we could draw a line more sharply between the pure nephritic and hepatic cases of eclampsia than ever before. At the Manhattan Maternity Hospital the internes often made the diagnosis of the nephritic or the hepatic varieties before urinary analysis. There was a small class of cases in which the urinary findings often flew the red flag, giving out the danger signal before the clinical condition and picture were particularly well marked. Suture of the cervix should be confined to those cases in which there was a hæmorrhage following labor. The keynote of the obstetric papers was prophylactic obstetrics. It was Utopian to believe that we had arrived at a condition of affairs where dystocia would be prevented weeks before labor set in. In institution work the mortality from puerperal sepsis was one tenth of one per cent. or less. The morbidity was exceedingly low. This was not so in private practice.

The reason for this diminution in the mortality and morbidity rate in institutions was the introduction of asepsis and antiseptics in midwifery. The inference was plain. Ophthalmia neonatorum in institution work gave a mortality that was practically nil; but this was not so in private work. In England, in 1894, thirty-four per cent. of the cases of total blindness were due to ophthalmia neonatorum. Twelve years later, in New York State, in 1906, twenty-six per cent. of the cases of blindness were found to be due to this cause. Examinations in pregnancy, especially in the primigravida, were of value in determining contracted pelvis or large children; this was carried on only in institutions.

In speaking of the advances in midwifery he said he could merely refer to a box on the table before the academy, the property of Dr. Bedford, who died in his sixty-fourth year in 1870 or thereabouts. He would simply state that the top tray contained eleven

instruments; of these eleven, ten were designed to mutilate the child, or break it up, and only one was for the delivery of a living child.

Dr. CHARLES JEWETT said that in the toxæmia of pregnancy, whether of the vomiting or eclamptic type, the general condition of the patient must still remain the principal guide in the treatment. As Ewing and Wolf had stated, any material departure from the normal nitrogen ratios spoke for an unstable condition of the organism that might end in disaster. Eclampsia sometimes occurred explosively with scant clinical premonition. The end might come unexpectedly in pernicious vomiting. An elaborate analysis of the urine at short intervals during pregnancy, in the latter months, and in all cases of pregnancy vomiting, might save many lives, but this required the services of a practical chemist, so that this was expensive and not generally available. He would like to have heard more said regarding the nitrogen coefficient as a clinical guide; the objection had been made against it that an increase in the proportion of ammonia nitrogen might be due to starvation rather than pregnancy toxæmia. Experimental liver necrosis in animals, so long as the animals could be fed, was attended with very little increase in the ammonia excretion, while in the hyperemesis of pregnancy in the human subject, even with comparatively little pathological change in the liver, the percentage of ammonia nitrogen often was in great excess. Pubic section, whether median or extramedian, had a limited field, and it had grown more so with the improvement in the status of the Cæsarean section. It was difficult to select cases before labor which we could be sure would properly fall within the scope of symphysiotomy or hebotomy. The principal objection to immediate suturing of the cervix was the danger of sepsis. The cervix was perhaps the seat of less resistance than other parts of the birth canal, because of the traumatism it suffered even in spontaneous delivery. The cervix should not be sutured at the end of labor except when it was necessary for hæmostasis.

Dr. GEORGE L. BRODHEAD said that cases would be met with from time to time in which the clinical picture suggested that the uterus be not emptied, in spite of the fact that the urinary findings indicated the termination of pregnancy. We were becoming more and more accustomed to doing craniotomy in cases where the child was dead, rather than to subject the woman to a difficult forceps operation or version. Lacerated cervixes should be repaired immediately after delivery only in cases of hæmorrhage. Cæsarean section might be done too often. Many patients might be delivered at the eighth month safely and well. After Cæsarean section the danger of rupture occurring at the site of the scar in subsequent labors should be borne in mind. Therefore the induction of premature labor offered an advantage over Cæsarean section. Too much attention could not be given to the details of obstetric work.

Dr. F. A. DORMAN emphasized the clinical evidences of toxæmia, so often overlooked by the general practitioner. The excretory and digestive functions, the circulatory system, and the nervous manifestations, neuralgic or mental, should be carefully investigated. The operation of instrumental rotation of the head was a valuable method and tech-

nique in occipitoposterior positions, and was increasing in usefulness. Rubber gloves should be used as a prophylactic measure. The induction of premature labor had a large field, and very successful results might be obtained by starting labor while the child was smaller.

Dr. W. GILL WYLIE said that it had been his practice for over twenty-five years to make a close study of all these cases from the beginning, and it was amazing how often cases of toxæmia and septic troubles could be averted. The prevention of disease offered great future advances.

Dr. JAMES EWING said that the estimation of the nitrogen partition was not presented to supersede other and older methods, nor was it intended to tell when to empty the uterus; it only told when metabolism was not right. The estimation of the nitrogen partition should be made the basis of treatment to prevent the necessity of emptying the uterus.

Dr. EDWIN B. CRAGIN believed that the elective vaginal Cæsarean section had but a small field.

Dr. HERMANN J. BOLDT said that the adenomatous type of chorioepithelioma might sometimes be as dangerous to life as the carcinomatous type. In his opinion it was in the interests of the patient to do radical work on the basis that we were dealing with a malignant form of disease.

Dr. EDWARD REYNOLDS, speaking of the mortality of Cæsarean section being raised in proportion to the length of labor, made the simile as follows: If one hundred strong men started to do a twenty-five mile Marathon run, and a certain proportion pulled out at the end of one mile and subjected themselves to an operation, say an appendectomy, would they not expect that mortality to be less than if done on those who struggled in at the finish?

## Letters to the Editors.

### MANUAL THERAPEUTICS.

1504 PINE STREET, PHILADELPHIA, March 21, 1908.

To the Editors:

Will you permit me to reply to the large number of inquiries concerning my article in the February 8th issue, on *The Hand as a Therapeutic Agent*? I am asked: "How can a physician learn what is necessary to make use of the hand in securing the results alluded to?"

First of all, it is essential to have a working knowledge of the physiology of circulation, especially the vasomotor mechanisms.

It would undoubtedly be best for any one desiring to attempt this form of auxiliary treatment to know the art of manipulation practically. It would be well to secure as teacher a graduate of the Royal Institute of Stockholm if possible; if not, then the best masseur obtainable.\*

There are many excellent books dealing with the subject of massage, and from which much can be learned, as Douglas Graham, J. H. Kellogg, Thomas Stretch Dowse, Hartvig Nissen, Professor Landreer, Kleen, etc. John P. Arnold, who died recent-

\*I have not a personal knowledge of any one who is qualified to teach this subject in this country. There are some who are qualified in Europe, and who are well known.

ly, had nearly completed a book on *Clinical Physiology*, which contains data to elucidate the vaso-motor reactions necessary to a comprehension of the principles involved. There are a number of books by reputable authors, dating back as far as 1834, notably the one by the two brothers Griffin, published in that year, in which are analyzed 148 cases. My friend Dr. Seymour D. Ludlum (of 1728 Chestnut street, Philadelphia) read an admirable paper before the American Medical Association last June (just now passing through the press), which gives further information on history and physiology.

We must be prepared to learn from irregular, as well as regular sources of knowledge. Some of these practitioners attain excellent skill, and they oftentimes get admirable results. I do not find that they differ materially in their physical methods from those of the high class Swedish masseurs. All this utility, however, is entirely within the province and capacities of a properly educated physician, provided he possesses dexterity.

It is by no means necessary to assume, as many do, that much time or strength is demanded in accomplishing desired effects. I am able to materially relieve and oftentimes to cure ailments, not otherwise relievable, by a two or three, or possibly five or ten minutes' procedure, requiring exceedingly little effort, yet valuably supplementing whatever knowledge I possess of the use of hygiene, drugs, electricity, moral suasion, and other commonly employed therapeutic measures.

The important point is that physicians should learn, by practice, enough of these procedures for their own use. They cannot fail to prove of inestimable value, fitting them to form standards whereby they can select and direct those who shall apply the treatment. Furthermore, it is well to remember that one cannot learn to play the violin without employing thought, study, and considerable experience.

Finally, unless physicians recognize the truth, as I hope I have set it forth in my paper, they will constantly be annoyed by losing the confidence of their patients, and, worst of all, omit to supply that measure of resourcefulness, leading up to satisfactory results, which is entirely within their powers if they will give the subject a moderate degree of personal attention.

J. MADISON TAYLOR.

### Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

*Lectures on Medical Jurisprudence and Toxicology*, as Delivered at the London Hospital. By FRED. J. SMITH, A. M., M. D. Oxon.; F. R. C. P. Lond.; F. R. C. S. Eng.; Physician to and Lecturer on Forensic Medicine at the London Hospital, etc. Second Edition. London: J. & A. Churchill, 1908. Pp. xiv-463. (Price, \$3.40.)

Though this comparatively small book does not purport to be anything like a complete treatise, it expounds the gist of the subject very satisfactorily, and we do not wonder that a second edition has been called for. The principal additional matter is in the form of three new lectures—The Examina-

tion of the Person Alive and Dead, Death Certification, and Anaesthetics. The entire volume teems with common sense and with the desire to smooth out difficulties for the practitioner of medicine in situations where he may come in contact with the law. It contains much spicy material, especially in the running commentary on the *Coroner's Catechism*, a set of questions drawn up by coroners for routine use in cases of death imputed to the administration of an anæsthetic. We can heartily commend the book.

*A Textbook on Prescription Writing and Pharmacy. With Practice in Prescription Writing, Laboratory Exercises in Pharmacy, and a Reference List of the Official Drugs, Especially Designed for Medical Students.* By BERNARD FANTUS, M. D., Professor of Materia Medica and Therapeutics, College of Physicians and Surgeons of Chicago, etc. Second Edition, Thoroughly Revised and Adapted to the Eighth (1905) Edition of the United States Pharmacopœia. Chicago: Chicago Medical Book Company, 1906. Pp. 404.

Numerous are the books which have been compiled with the object of supplying medical students with the knowledge they are supposed to acquire of the art of prescription writing and the compounding of drugs during their college course, but few are found to fulfil their purpose. The failure does not always spring from a lack of acquaintance with correct methods on the part of the authors, but is the result in most instances of a faulty arrangement of the subject matter which is confusing to the student. Of the lack of what the Germans call *Gefühl* for the study of pharmaceutical principles in teachers of materia medica and therapeutics, a feeling which cannot be developed in students except by teachers who possess it themselves in a sensitive and trustworthy form, it is mentioned here only to emphasize the fact that textbooks which do not give evidence of the possession of this feeling by their authors are usually unsatisfactory guides. In the work by Dr. Fantus indications are plentiful of the author's intimacy with the technique of the dispensing pharmacist, and he makes use of and exhibits his intimate acquaintance with the drugs and medicines of the pharmacopœia in a manner that is admirably adapted, we think, for the training of medical students along well ordered lines. The design and scope of his work are such as to make for orderly and systematic study, and a multiplicity of details, which is apt to be so confusing to the student, is avoided, without, however, any sacrifice of essentials. The form, language, and composition of prescriptions are dealt with in the beginning, prescription ethics being also considered in chapters on the repeating, ownership, and cost of prescriptions, in which useful hints are given regarding the customs of both prescribers and dispensers. The chapters in which the products of pharmacy are described impress the reviewer as being eminently practical, and the student who masters them should never be at a loss to know what is required in the origination of a prescription for any single drug or combination of drugs. Laboratory exercises are outlined, the numerous problems in prescription writing and compounding being calculated to form excellent drilling in these subjects.

As a textbook of materia medica the book is thorough, yet concise. Nearly one half of it is taken up

with descriptions of drugs, arranged in a form to facilitate memorizing by the student. First is given the official Latin name of the drug, printed in Gothic capitals, and followed by (1) the pronunciation, (2) the genitive case, (3) the official English name, (4) synonyms, (5) the origin of vegetable drugs, (6) a description, (7) solubility, (8) active constituents, (9) incompatibles, (10) uses, (11) doses, (12) official preparations, and (13) forms of administration. It only remains to add that the volume is in accord with the latest revision of the United States Pharmacopeia, and is a manual of prescription writing and pharmacy that can be unqualifiedly commended for use as a textbook of these subjects in medical colleges. Although it is dated 1906, it is only within a few weeks that we have received it.

*Schema des Rumpfes.* Von Privatdozent Dr. W. HILDEBRANDT, Freiburg i. B. Taschenausgabe. München: J. F. Lehmann, 1908. (Price, 1.20 mark.)

This booklet, in the form of a pad, consists of about twenty-five pages, each of which can easily be detached and used as a memorandum, taking the place of a written case history. Each of the pages contains a diagram of the skeleton of the trunk, with landmarks, drawn similar to the Mercator projection map of the earth. The physician is to mark in this schedule certain lines and arrows indicating the situation of the viscera as found in the patient under examination, together with the results of auscultation and percussion depicted in graded shading, and using certain forms of lines and cross hatchings which are explained on the fly leaf of the pad.

*The Practice of Gynecology*, in Original Contributions. By American Authors. Edited by J. WESLEY BOVÉE, M. D., Professor of Gynecology, George Washington University, Washington, D. C. Illustrated with 382 Engravings and 60 Full Page Plates. New York: Lea Brothers & Co. Pp. xii-836.

This volume, one of three to cover the subjects of pædiatrics, obstetrics, and gynecology, is an eminently characteristic contribution to American gynecological literature. An incomplete list of the authors and their contributions will substantiate this view. Thus, Dr. Bovée has written of developmental anomalies and the diseases and affections of the urinary system; Dr. X. O. Werder has contributed articles on the examination of patients and on extrauterine pregnancy; Dr. J. Riddle Goffe has written on menstruation, uterine displacements, and the vaginal method of operating; Dr. G. H. Noble has written of fecal and urinary fistulæ and lacerations; and Dr. Benjamin R. Schenck and Dr. Thomas J. Watkins have divided the diseases of the Fallopian tubes between them. Dr. G. B. Miller has taken the tumors and inflammations of the uterus for his subjects.

The book is remarkably free from the repetition and overlapping that one usually finds in composite works. While it is not possible in a short space to review each series of contributions, the general conservative attitude of the authors is to be commended. Thus, the avoidance of unnecessary instrumental manipulation of the uterus is advised, as well as the nonoperative treatment of acute infections involving the uterus and appendages. The

chapter on postoperative treatment and the complications of abdominal operations is unusually good. The vaginal operations are, too, very well described, as are the various methods of repair of vaginal and perineal tears. Among other features, the details of plastic operations on the tubes may be mentioned with commendation.

Altogether, much care and toil have gone into the preparation of this book. Not only textually, but as far as the illustrations are concerned as well, can the volume be heartily commended as a practical work on gynecology from the standpoint of the American gynecologist of to-day.

*Skin Affections in Childhood.* By H. G. ADAMSON, M. D. (Lond.), M. R. C. P., Physician for Diseases of the Skin, Paddington Green Children's Hospital, etc. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1907. Pp. xvi-287.

Although the skin affections in children are essentially the same as those in adults and should be taught as an intimate part of the whole subject of dermatology, there are many advantages in considering them apart. Many affections of the skin are far more prevalent in childhood than in adult life, while others are peculiar to the child, or, when occurring in childhood, are so modified that they present entirely special appearances. This book is therefore a useful addition to our compendia in dermatology.

The author treats his subject from the clinical, diagnostic, and therapeutical points of view, and divides it thus: Affections of congenital origin; eruptions due to local physical causes, animal and vegetable parasites, local microbic infection, or toxic origin; tuberculous disease of the skin; affections of nervous origin; and, finally, unclassified affections. On pages 280 to 284 will be found a very handy list of the principal remedies for external applications. The illustrations are good selections and are well executed.

*Die chirurgischen Untersuchungsarten.* Einführende Vorlesungen über allgemeine chirurgische Diagnostik von Dr. OTTO MANZ. Mit 38 Abbildungen im Texte. II. Teil. Jena: Gustav Fischer. Pp. vii-257.

The object of these lectures is the instruction of the student in the methods of examining surgical patients. They are simple and very complete, omitting unnecessary and unimportant facts in order to emphasize the essential features of surgical diagnosis. In other words, it is a work on *surgical* physical diagnosis. The author has sensibly avoided long descriptions of technical processes, such as cystoscopy and œsophagoscopy, but has contented himself with the laying down of broad general principles.

The book is worthy of study, and will prove valuable to moderately advanced students as well as to teachers in the preparation of their lectures. The illustrations are particularly well chosen.

*Physiology and Pathology of the Urinary and Biliary Systems.* By Dr. L. A. FINE, Professor of Medicine, University of California, Los Angeles, and at University of California, Berkeley, J. F. Rogers, Ph.D., etc.

There is no doubt that, within the past five years, Fine's method of staining the organs with carmalum has been a recognized innovation.

been widely accepted by the profession as a valuable therapeutic measure. Especially in the treatment of uterine hæmorrhages has this procedure seemed to be of benefit. Thus, in hæmorrhages preceding the menopause, in hæmorrhagic endometritis, in bleeding due to hæmophilia, and in cases of uterine fibroids (except of the submucous variety), the use of atmocausis is almost invariably attended with success. Pincus, in this edition, advises that the procedure be preceded by curetting, sufficient time being allowed for regeneration of the endometrium to take place. In ordinary endometritis atmocausis seems to be of no benefit, and in septic cases, too, it has shown little favorable result; but in the conditions mentioned and in menorrhagia or metrorrhagia depending upon postabortive subinvolution, chronic uterine atony, as well as for the production of sterility, and for the cure of chronic gonorrhœal endometritis, it is of the greatest value.

Pincus is careful to urge a selection of the cases in which atmocausis should be used. The book represents a thorough and careful clinical and pathological study.

#### BOOKS, PAMPHLETS, ETC., RECEIVED.

**Life Insurance and General Practice.** By E. M. Brockbank, M. D. (Vict.), F. R. C. P., Honorary Assistant Physician, Royal Infirmary, Manchester, etc. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1908. Pp. xiv-288.

**Darwinism To-day.** A Discussion of Present Day Scientific Criticism of the Darwinian Selection Theories, Together with a Brief Account of the Principal Other Proposed Auxiliary and Alternative Theories of Species Forming. By Vernon L. Kellogg, Professor in Leland Stanford, Jr., University. New York: Henry Holt & Co., 1907. Pp. xii-403.

**Diseases of the Lungs.** Designed to be a Practical Presentation of the Subject for the Use of Students and Practitioners of Medicine. By Robert H. Babcock, A. M., M. D., Author of *Diseases of the Heart and Arterial System*, Consulting Physician to Cook County Hospital, etc. With Twelve Colored Plates and One Hundred and Four Text Illustrations. First Edition. New York and London: D. Appleton & Co., 1907. Pp. xix-89.

**Gonorrhœa. Its Diagnosis and Treatment.** By Frederick Baumann, Ph. D., M. D., Professor of Genitourinary Diseases in the Reliance Medical College, and Instructor in Dermatology and Venereal Diseases in the College of Physicians and Surgeons, Chicago. Fifty-two Illustrations in the Text. New York and London: D. Appleton & Co., 1908. Pp. xii-206.

**An Introduction to Vegetable Physiology.** By J. Reynolds Green, Sc. D., F. L. S., F. R. S., Fellow of Downing College, Cambridge, Late Professor of Botany to the Pharmaceutical Society of Great Britain, etc. Second Edition. Philadelphia: P. Blakiston's Son & Co., 1907. Pp. xx-459.

**Die Funktionen der Nervencentra.** Von Prof. Dr. W. v. Bechterew, o. Akademiker, Direktor der psychiatrischen und Nervenkl. der medizinischen Akademie, Präsident des psychoneurologischen Institutes in St. Petersburg. Deutsche Ausgabe, in Verbindung mit dem Verfasser redigiert durch Dr. Richard Weinberg, Professor der Anatomie in St. Petersburg. Erstes Heft: Einleitung, Untersuchungsmethoden, Rückenmark und Verlängertes Mark. Mit 66 Abbildungen im Text. Jena: Gustav Fischer, 1908. Pp. 691.

**The Bacteriology of Diphtheria.** Including Sections on the History, Epidemiology, and Pathology of the Disease, the Mortality Caused by it, the Toxines and Antitoxines, and the Serum Disease. By F. Loeffler, M. D., LL. D.; Arthur Newsholme, M. D., F. R. C. P.; F. B. Mallory, M. A., M. D.; G. S. Graham-Smith, M. A., M. D., D. P. H.; George Dean, M. D.; William H. Park, M. D., and Charles F. Bolduan, M. D. Edited by G. H. F. Nuttall, M. D., Ph. D., Sc. D., F. R. S., Quick Professor of Biology in the University of Cambridge, Fellow of Christ's College, and G. S. Graham-Smith, M. A., M. D., University Lecturer in

Hygiene, Cambridge. Cambridge: University Press, 1908. London: H. K. Lewis. Leipzig: F. A. Brockhaus. New York: G. P. Putnam's Sons. Bombay and Calcutta: Macmillan & Co., Ltd. Pp. xx-718. (Price, \$7.50.)

**Bier's Hyperæmic Treatment in Surgery, Medicine, and the Specialties. A Manual of Its Practical Application.** By Willy Meyer, M. D., Professor of Surgery at the New York Postgraduate Medical School and Hospital, etc., and Professor Dr. Victor Schmieden, Assistant to Professor Bier, University of Berlin, Germany. Illustrated. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 209. (Price, \$3.)

### Miscellany.

**Proposed State Custodial Institution at Haverstraw, N. Y.**—The following resolution was unanimously passed at a regular meeting of the Medical Society of the County of New York, held on March 23, 1908; submitted to the members by Dr. E. Eliot Harris, chairman of the Committee on Legislation:

*To the president and members of the Medical Society of the County of New York:*

The Committee on Legislation voted unanimously to actively support Senate Bill No. 636 and Assembly Bill No. 1215, and requested its chairman to prepare suitable resolutions to be submitted to the society for its action.

Whereas, the commission appointed by his Excellency Governor Hughes, pursuant to an act of the last Legislature, has investigated and reported on a suitable site for the Eastern New York State Custodial Asylum, and has officially published that there are at least 20,000 feeble minded and epileptic persons in this State; that the existing State custodial institutions located at Rome, Syracuse, Newark, and Sonyea are now overcrowded; that they house 3,250 persons while their capacity is authoritatively reported for only 3,183 inmates, making an excess of 67 persons, which, added to 1,000 applicants who are now on the waiting list of these institutions, and 1,808 patients improperly confined in almshouses of the State, make a total of 2,875 patients needing immediate State custodial care—to say nothing of the much larger number of 20,000 persons in private homes who require State custodial care for the protection of themselves and for the protection of the best interests of the Commonwealth.

Whereas, the site selected is admirably suited for the purposes of the colony, as shown in the report of Mr. Kuichling, the consulting engineer; the options on the property were secured at a time which gives the State a remarkable opportunity to be possessed of a tract of land at the lowest possible cost; its value will rapidly enhance with the improvement in the financial conditions of the county; that the proposed colony will be located near Haverstraw, Rockland County, 22 miles north of New York City, is a great blessing to these unfortunate poor as well as being of great economic value to the State, as it may be readily and cheaply reached by train or boat; the round trip being one dollar by train and much less by boat; that more than fifty per cent. of the inmates and over sixty-one per cent. of those on the waiting lists of the distant State institutions are from the vicinity of Greater New York accounts for the many instances where it seems cruel to send these poor patients so far from their family relations and friends, who plead pitifully for their retention in the city institutions which are accessible to them, for they know full well that the time and the expense of the journey will in most cases prohibit them from ever seeing their dear ones again, which becomes evident when we consider that the round trip railroad fare alone is fourteen dollars to the Craig Colony for Epileptics at Sonyea—the present cost to the Department of Public Charities of this city to send a patient with an attendant to the colony is over twenty-five dollars. If a colony was established at Haverstraw then the regular boat of the Department could make the trip easily and without cost to the visitors entitled to permits.

Therefore, be it resolved, that this society earnestly requests the finance committee of the senate to report favor-

ably Senator Armstrong's bill No. 636, which provides for an appropriation of one hundred and eighty-eight thousand five hundred and seventy-five dollars for the site near Haverstraw, Rockland County. The members of the Senate are also urgently requested to vote for the final passage of the bill which has already passed the assembly unanimously as Assembly Bill No. 1215.

Resolved, that the Committee on Legislation be empowered to use these resolutions in cooperating with other committees working for the enactment of the bill to purchase the site of the Eastern New York State Custodial Asylum.

## Official News.

Public Health and Marine Hospital Service  
Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon general, United States Public Health and Marine Hospital Service, during the week ending March 27, 1908:

Places.	Date.	Cases. Deaths.
Alabama—Mobile	March 7-8	1
California—Los Angeles	Feb. 29-March 7	10
California—San Francisco	Feb. 29-March 7	12

### Army Intelligence:

Official list of changes in the stations and duties of officers serving in the medical department of the United States Army for the week ending March 28, 1908:

BANISTER, W. B., Major and Surgeon. Appointed a member of a board of officers, to meet at the call of the president thereof at Manila, P. I., for the examination of such officers of the Medical Department, ordered before it to determine their fitness for promotion.

BORDEN, W. C., Major and Surgeon. Appointed a member of a board of officers, to meet at the call of the president thereof at Manila, P. I., for the examination of such officers of the Medical Department, ordered before it to determine their fitness for promotion.

BROWNLEE, C. Y., First Lieutenant and Assistant Surgeon. Relieved from duty at the Pacific Branch, U. S. Military Prison, Alcatraz Island, Cal., and ordered to Manila, P. I., for duty on transport to sail from San Francisco, Cal., about May 5, 1908.

DELOFFRE, S. M., First Lieutenant and Assistant Surgeon.  
Leave of absence extended seven days.

DEWITT, W., First Lieutenant and Assistant Surgeon. Ordered to Fort Yellowstone, Wyo., for duty upon expiration of present leave of absence.

GIBNER, H. C., First Lieutenant and Assistant Surgeon. Ordered to report at the Army General Hospital, Presidio, San Francisco, Cal., for temporary duty.

GLENNAN, J. D., Major and Surgeon. Appointed a member of a board of officers, to meet at the call of the president thereof at Manila, P. I., for the examination of such officers of the Medical Department ordered before it to determine their fitness for promotion.

GREENLEAF, H. S., Captain and Assistant Surgeon. Granted four months' leave of absence with permission to go beyond the sea.

GRISSINGER, J. W., Captain and Assistant Surgeon. Granted two months leave of absence.

KENDALL, WILLIAM P., Major and Surgeon. Relieved from duty at Fort Sam Houston, Tex., and will proceed to Fort Riley, Allen, Mo., at that point.

leave of absence for fifteen days, to take effect upon his arrival at Madison Barracks, N. Y., with troops from San Francisco, Cal.

STAFF: A. N. Major and Surgeon. In addition to his other duties at Vancouver Barracks, Wicks will assume temporary charge of the staff of the Chief Surgeon, Department of the Columbia.

Wounded by J. T. Carson and Assistant Surgeon. Relieved on duty in the Philippine Division, and will proceed on his tour of duty in all three. Major F. J. Chase, Surgeon, 1st San Francisco, will report in person, will report to the Adjutant General of the Army the next morning.

**Navy Intelligence:**

*Official list of changes in the medical corps of the United States Navy for the week ending March 28, 1908:*

- ALDERMAN, C. G., Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to the *South Dakota*.
- BAKER, M. W., Passed Assistant Surgeon. Detached from the Naval Hospital, New York, N. Y., and ordered to the *Colorado*.
- BARBER, G. H., Surgeon. Detached from the Naval Hospital, Boston, Mass., April 10th, and ordered to instruction at the Naval Medical School, Washington, D. C.
- BLACKWELL, E. M., Passed Assistant Surgeon. Detached from the Naval Academy and ordered to instruction at the Naval Medical School, Washington, D. C.
- BOGERT, E. S., Jr., Surgeon. Orders of March 10th modified; ordered to course of instruction at the Naval Medical School, Washington, D. C.
- BOLAND, M., Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to the naval recruiting station, Detroit, Mich.
- BUNKER, C. W. O., Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to the Naval Academy, Annapolis, Md.
- CLAYTON, J. C., Acting Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to report before the naval medical examining board, that city, April 1st, for examination for appointment as assistant surgeon, and then to await orders.
- COLE, H. W., Jr., Assistant Surgeon. Detached from the Navy Yard, Charleston, S. C., and ordered to instruction at the Naval Medical School, Washington, D. C.
- DUBIGG, J. T., Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to the naval recruiting station, Des Moines, Ia.
- FAUNTILEROV, A. M., Passed Assistant Surgeon. Detached from the Naval Medical School Hospital, Washington, D. C., and ordered to instruction at the Naval Medical School, that city.
- FISKE, C. N., Passed Assistant Surgeon. Detached from the Naval Hospital, Mare Island, Cal., and ordered to course of instruction at the Naval Medical School, Washington, D. C.
- FREEMAN, G. F., Passed Assistant Surgeon. Detached from the Naval Hospital, Portsmouth, N. H., and ordered to instruction at the Naval Medical School, Washington, D. C.
- HALE, G. D., Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to the *Idaho*.
- HAYDEN, R., Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to duty with the marine detachment at Camp Columbia, Cuba, sailing from New York, N. Y., about April 4th.
- HERMESCH, H. R., Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to the naval recruiting station, Cincinnati, Ohio.
- HUFF, E. P., Assistant Surgeon. Detached from the naval proving ground, Indian Head, Md., and ordered to the naval station, Olongapo, P. I., sailing from San Francisco, Cal., about May 5th.
- HUFFMAN, O. V., Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to the *New Hampshire*.
- LANDO, M. E., Assistant Surgeon. Detached from the naval station, Tutuila, Samoa, and ordered home to await orders.
- MCDONALD, P. E., Passed Assistant Surgeon. Detached from the *Connecticut* and directed to await orders.
- MCLEAN, A. D., Passed Assistant Surgeon. Detached from the naval recruiting station, Detroit, Mich., and ordered to the Navy Yard, Portsmouth, N. H.
- PECK, A. E., Passed Assistant Surgeon. Detached from the naval station, Olongapo, P. I., and ordered home to await orders.
- RANDALL, J. A., Passed Assistant Surgeon. Detached from the naval recruiting station, Denver, Col., and ordered to the *Denver*.
- SMITH, F. W., Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to the *Hesperus*.
- SMITH, G. T., Surgeon. Detached from the *Maryland*, April 1st, and ordered to instruction at the Naval Medical School, Washington, D. C.

- SPEAR, D. A., Assistant Surgeon. Detached from duty at the Naval Medical School, Washington, D. C., and ordered to the Naval Hospital, New Fort Lyon, Col.
- STAPP, J., Passed Assistant Surgeon. Detached from the *Denver* and ordered home to await orders.
- STIBBENS, Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to the Naval Hospital, Mare Island, Cal.
- STUART, M. A., Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to duty at Camp Elliott, Isthmian Canal Zone, sailing from New York, N. Y., about April 7th.
- TAYLOR, J. L., Assistant Surgeon. Detached from duty with the marine detachment at Camp Columbia, Cuba, and ordered to instruction at the Naval Medical School, Washington, D. C.
- TRIBLE, C. B., Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to the Naval Hospital, Mare Island, Cal.
- VALZ, E. V., Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to the *Mississippi*.
- WICKES, G. L., Assistant Surgeon. Detached from the naval recruiting station, Omaha, Neb., and ordered to the naval recruiting station, Denver, Col.
- WILSON, G. B., Surgeon. Detached from the *Wabash* and ordered to instruction at the Naval Medical School, Washington, D. C.
- WOODWARD, J. S., Passed Assistant Surgeon. Detached from the naval recruiting station, Cincinnati, Ohio, and ordered to the Naval Hospital, New York, N. Y.

The following medical officers were detached from the Naval Medical School, Washington, D. C., and ordered to duty as specified below:

- HIGGINS, S. L., Assistant Surgeon. To the Naval Hospital, Canacao, P. I., sailing from San Francisco, Cal., about May 5th.
- KELLEY, H. L., Assistant Surgeon. To the Naval Hospital, Canacao, P. I., sailing from San Francisco, Cal., about May 5th.
- LAWRENCE, H. F., Assistant Surgeon. To the naval station, Tutuila, Samoa, and to additional duty on board the *Annapolis*, sailing from Vancouver, B. C., about April 24th.
- ROSE, M. E., Assistant Surgeon. To the naval recruiting station, Omaha, Neb.
- SHORT, W. H., Assistant Surgeon. To the naval recruiting station, Oklahoma City, Okla.
- STRAETON, R. J., Assistant Surgeon. To the naval station, Guam, L. I., sailing from San Francisco, Cal., about May 5th.

## Births, Marriages, and Deaths.

### Died.

- BAKER.—In Philadelphia, on Friday, March 20th, Dr. George Linville Baker.
- BARRETT.—In Louisa, Virginia, on Tuesday, March 17th, Dr. R. L. Barrett, aged seventy-five years.
- BURLEIGH.—In Braintree, Massachusetts, on Saturday, March 21st, Dr. Robert F. Burleigh, aged forty-six years.
- BUTMAN.—In Somerville, Massachusetts, on Sunday, March 22d, Dr. George F. Butman, aged seventy years.
- COOK.—In Chicago, on Saturday, March 21st, Dr. John C. Cook, aged fifty-eight years.
- DEWEY.—In Chicago, on Monday, March 23d, Dr. Frank Jones Dewey, aged fifty-seven years.
- FORD.—In Washington, Connecticut, on Friday, March 27th, Dr. William J. Ford, aged fifty-eight years.
- LITTELL.—In Rye, Colorado, on Monday, March 16th, Dr. R. S. Littell.
- MCCONNELL.—In Ludington, Michigan, on Tuesday, March 24th, Dr. A. P. McConnell, aged eighty-two years.
- MORSE.—In Boston, on Tuesday, March 24th, Dr. Edward G. Morse.
- PEASE.—In Springfield, Massachusetts, on Monday, March 23d, Dr. Herbert Owen Pease, aged fifty-nine years.
- TETZEL.—In Cleveland, Ohio, on Wednesday, March 18th, Dr. William McQueen Tetzell.
- VENN.—In Chicago, on Monday, March 23d, Dr. Clement Venn, aged forty years.

### Original Communications.

#### A CASE OF PERNICIOUS MALARIA WITH AUTOPSY.\*

By G. R. SATTERLEE, M. D.,  
New York.

This case is interesting because of the infrequency of tropical malarial fever in the northern part of this country and the still more infrequent reports of autopsies on these cases.

The patient, a Finn, twenty-six years old, was admitted to the wards of Gouverneur Hospital, New York, on October 15, 1907, at 9 p. m., in the service of Dr. Francis Huber. His condition was so grave and his knowledge of the English language so poor that a very imperfect history only was obtained. He was a sailor and had spent the last six months traveling around South America (in places the names of which were unobtainable) and had been in this city for nine days following his return from the last trip south. He had been a heavy drinker, but denied any severe illnesses. He gave no distinct malarial history with the exception that he stated that he had, a week before admission, loss of appetite, headache, chilly sensations, general malaise, fever, some localized pain in the epigastrium and diarrhoea. He was brought to the hospital during a chill in a state resembling alcoholic delirium. On admission his temperature was 105.4° F., pulse 120, and respiration 42. His temperature dropped rapidly to 99° F., his condition improved, and although he was semidelirious, seemed to understand questions (see temperature chart).

He was a well developed and well nourished man, with a slight icteroid hue to the skin. Slight epigastric tenderness was present, the liver could not be felt, and the spleen was just palpable.

The blood examination on the second day after admission showed 24,000 leucocytes per c.mm. with 56 per cent. polynuclear, 11 per cent. large mononuclear leucocytes, and 32 per cent. lymphocytes. No red blood cell count nor estimation of haemoglobin was made.

The blood examination for malaria, sixteen hours after entrance, showed an excessive number of signet ring forms of plasmodia. The urine contained no albumin, blood, nor casts. The diagnosis of malarial fever and alcoholism was made, and quinine sulphate was administered in large doses by mouth.

On the morning of the second day the temperature rose rapidly to 103° F. and remained there all day. His mental condition during the afternoon was that of apathy and gradually merged into coma. Shortly before midnight of the third day under observation he had a chill lasting twenty minutes, followed by a rise of temperature to 105.8° F., pulse of 140, and succumbed.

Blood smears were examined sixteen hours, twenty-four hours, and forty hours after entrance chill and just after death.

The blood taken twenty-four hours after the entrance chill showed in the red blood corpuscles an excessive number of signet ring forms of the asexual malarial parasite (see Fig. 1).

The rings were small, occupying about one sixth of the area of the erythrocyte; in the early stages with thin bodies and a small amount of fine pigment and one nucleus; in the later stage with thicker bodies, more pigment, and occasionally two or more nuclei. Many of the parasites were near the edge of the cell with the nucleus protruding

Temperature chart. Asexual malarial fever, pernicious type.

into the cell wall. Nearly 75 per cent. of the erythrocytes contained parasites, very many with two, many with three, and some with four organisms. The infected cells were small and shrunken, their cytoplasm dark and many crenated, and there was a marked absence of granular degeneration.

Fig. 2 shows the organism of simple tertian malarial fever in a pale enlarged erythrocyte which can be contrasted with that of the pernicious type.

The blood examined eight hours before death or forty hours after entrance showed but few plasmodia in the form of well developed signet rings, and a few occurring from one to four in a cell. There were numerous macrophages containing large amounts of black pigment, and some polymorphonuclear leucocytes with pigment along their rim (see Fig. 3). Macrophages, microcytes, and a few nucleated erythrocytes were present in this specimen. A few erythrocytes with partial extrusion were seen, suggesting beyond a doubt the asexual malarial form of the fever (see Fig. 4).

The blood examined at the time of death following the

\*Presented before the New York Pathological Society, November 11, 1907, and before the section in Medicine of the New York Academy of Medicine, February 8, 1908.

second chill or about forty-eight hours after the entrance chill) showed an excessive number of ring forms, often three or four in one corpuscle, crescents, ovoids, and nucleated red cells, signs evident of dissolution.

An autopsy was performed fifteen hours after death. The body was slightly jaundiced but showed no pigmentation of the skin or mucous membranes. The lungs showed a moderate congestion with edema at the bases. The

flattened rugæ and congested mucosa. There was marked congestion of the large intestine.

The spleen was enlarged, weighed one pound, and had a

FIG. 1.—Blood smear from a case of pernicious malaria, fourteen hours before death. Stained with Wright's stain. Oil immersion lens  $1/12$ , ocular 4. Camera lucida. *a*, Erythrocyte containing one well developed ring form; *b*, one with two; and *c*, one with three ring forms; *d*, ring form containing three nuclei. There is no granular degeneration of the corpuscles nor increase in their size.

pleural cavity was free from fluid. Microscopical examination demonstrated an intense congestion of the pulmonary capillaries, which contained numerous organisms in all stages, numerous macrophages, and free pigment. There was no general consolidation; some of the alveoli were free

FIG. 2.—Blood smear from a case of pernicious malaria, fourteen hours before death. Stained with Wright's stain. Oil immersion lens  $1/12$ , ocular 4. Camera lucida. *a*, Erythrocyte containing one well developed ring form; *b*, one with two; and *c*, one with three ring forms; *d*, ring form containing three nuclei. There is no granular degeneration of the corpuscles nor increase in their size.

from exudate, others contained quite a few leucocytes, pigmented epithelium, macrophages, and a small amount of fibrin.

The heart muscle was pale and flabby, the valves normal. The coronary arteries were normal. The aorta had a slight fatty infiltration of the intima. The arteries in general throughout the body showed very slight indications

The stomach showed a chronic atrophic gastritis with

FIG. 3.—Blood from a case of pernicious malaria, taken eight hours before death. Jenner's stain. Oil immersion  $1/12$ , ocular 4. Camera lucida. *a*, Erythrocyte containing one well developed ring form; *b*, erythrocyte with one full grown schizont; *c*, one with two full grown schizonts; *d*, macrophage. Note the small size of the infected corpuscles and the lack of granular degeneration.

moderate old interstitial splenitis with a few old cicatrices on the surface. The section revealed a small amount of interstitial connective tissue, and a pulp of moderately soft

FIG. 4.—Blood from a case of pernicious malaria, eight hours before death. Jenner's stain. *a*, Crescent; *b*, erythrocyte containing four schizonts.

consistency and of a deep red color. The organ did not indicate any severe long standing chronic malarial infection. Smears from the spleen will be described later.

The liver was much enlarged and weighed six and three quarter pounds. The surface and section showed marked congestion of the veins and the lobules were well mapped out. Microscopical examination showed cloudy swelling of the liver cells with brown pigmentation. The capillaries were markedly congested and contained numerous malarial organisms and masses of black pigment. Haemosiderin reaction was absent.

Smears from the fresh liver showed marked pigmentation of the liver cells, and in the erythrocytes numerous ring forms, fully developed schizonts, and segmentation bodies. Numerous micro- and macrogametocytes are present. The liver was evidently an organ in which an active development of the malarial organism took place.

The kidneys presented the appearance of acute congestion with a pale parenchyma and no gross interstitial changes. Microscopical examination revealed a quite marked cloudy swelling of the epithelium of the convoluted tubules, with some granular degeneration and breaking down of the cells. The capillaries of the glomeruli as well as the larger bloodvessels, especially the veins, were acutely congested and contained numerous intracellular parasites.

The pancreas on gross appearance was normal, but on microscopical examination showed deficiency of zymogen granules in the epithelium. The congested bloodvessels contained numerous organisms, macrophages, and black pigment granules.

The brain was apparently normal except for a moderate

cious type of organism that the ring forms are very small, and often occur as two or more in one corpuscle. When full grown they occupy up to two thirds the volume of the cell, which shows a ten-

FIG. 5.—Smear from the bone marrow in a case of pernicious malaria. Wright's stain. Oil immersion  $1/12$ ; ocular 4. Camera lucida. *a*, Microgametocyte; *b*, erythrocyte containing moderately developed schizont; *c*, intracellular segmenting bodies with twenty merozoites; *d*, free pigment.

congestion of the bloodvessels. Microscopically there was a moderate congestion of the capillaries and small arteries, which contained a proportionate number of organisms and pigment.

Smears from the bone marrow of the ribs showed a large number of microgametocytes, numerous ring forms and segmenting bodies and a large amount of free pigment in masses (see Fig. 5).

Smears from the spleen were stained with Wright's and Jenner's stain (see Figs. 6, 7, and 8).

Every stage in the asexual development of the parasite can be demonstrated (see Fig. 6). Here can be seen the early and late signet rings, schizonts, rosettes, and segmenting forms. The latter contain from fifteen to twenty-five merozoites. Many erythrocytes contain two, three, and four parasites.

Microgametes and microgametocytes were very numerous (see Fig. 7) and less numerous macrogametocytes. These are evidenced by their larger size, finer pigment, and more distinct vacuolation near the rim of the cell (see Fig. 8). Macrophages are especially numerous. Some hyaline bodies are also present.

Max Braun (1) says of the malignant or pernicious

FIG. 6.—Smear from the spleen in a case of pernicious malaria. Jenner's stain. Oil immersion  $1/12$ ; ocular 4. Camera lucida. *a*, Microgametocyte; *b*, segmenting bodies with from twenty to twenty-five merozoites; *c*, erythrocyte containing two signet ring forms; *d*, same with three; and *e*, one with four ring forms; *f*, macrophages.

dency to shrinking and is darker than normal. The number of merozoites varies from eight to twenty-four, the average between twelve and sixteen. In

FIG. 7.—Smear from the spleen in a case of pernicious malaria. Wright's stain. Oil immersion  $1/12$ ; ocular 4. Camera lucida. *a*, Microgametocytes; *b*, macrogametocytes.

south European and in tropical malaria, the organisms are very numerous in the circulating blood, but seldom so in a west African pernicious fever.

C. W. Daniels (2) says that sporulation in malignant malaria occurs almost exclusively in the internal organs. That in fatal cases, with cerebral symptoms, the sporulating and full grown forms can be observed in enormous numbers in the brain and in other organs, lungs, suprarenals, liver, etc., but rarely in the kidneys. He says that the pigment in cases of short duration is in fine granules only; cloudy swelling and fatty degeneration are the principal changes that occur in the viscera; and that the blood stasis in the capillaries in the brain causes the large part of the headache, drowsiness, and coma of the disease.

#### Conclusions.

(1) This was a case of acute malignant or pernicious malarial fever of the aestivoautumnal type (tertian form, according to Dr. Charles F. Craig, U. S. A.) (3).

(2) Death was caused by the overwhelming invasion of the blood by the parasite, and due possibly to the toxins evolved and not to acute cerebral congestion and thrombosis.

(3) The sporulation of the organism took place principally in the inner organs, especially in the spleen, liver, lungs, pancreas, bone marrow, and to a less extent in the kidneys.

(4) Alcoholism played a small part as a factor in the man's death.

(5) The gametes may not be seen in the peripheral circulating blood until just before death.

(6) The diagnosis of pernicious malaria can be made on the small size, dark cytoplasm, and shrinking of the cytoplasm of the infected corpuscles.

60 EAST SEVENTY-EIGHTH STREET.

#### REPORT OF A CASE OF SARCOMA OF THE CHORIOID.

BY ARTHUR J. HERZIG, M. D.,  
New York.

I deem it of sufficient interest to the profession to report this case of sarcoma of the chorioid, not that the malignancy of the case is important or rare, but that the case is unusual in that it has run an unusual course. The case is as follows:

Mr. H. struck his head against an iron pipe about March 24, 1907. About a week afterward he complained of a sudden diminution of vision, and consulted his family physician, Dr. H. Goldman, who referred the patient to me for examination. I first saw the patient on April 12, 1907.

Family and Personal History.—There is no history of rheumatism, tuberculosis, gout, diabetes, or syphilis. Patient has always been a healthy man, active in work, leading

an out of door life. His business is real estate, age fifty-six years.

Examination of the right eye revealed the following: Media clear. Pupillary reaction normal to light and convergence. Pupils of normal size and equal. The lens

FIG. 8.—Smear from the spleen in a case of pernicious malaria. Stained with Wright's stain. Oil immersion  $1/12$ , ocular 4. Camera lucida. a, Macrogametocyte; b, microgametocyte; c, segmenting form with sixteen merozoites.

showed several opacities in the periphery, but was clear in the center. Indirect examination showed a slight edema, just below the region of the disk. In the lower and nasal portion a marked detachment presented itself which was ill defined and whose outlines were irregular. The veins larger and fuller than normal and arteries of normal size. There was no arterial sclerosis. The detachment could not be seen by the objective examination. Tension of the eye was normal. Range of vision was lost in the upper and outer portions. Chorioidal vessels could not be seen over the detachment. Muscle balance normal. Sclera white and tense. Vision 20/200. Not improved. Near vision negative.

Examination of the left eye revealed the following: A normal fundus with normal vessels and normal disk. Pupillary reaction normal to light and convergence. Some slight opacities were present in the lower lens. Cornea was clear. Pupil of the same size as that of right eye. Tension normal. Muscle balance normal. Sclera white and tense. Range of vision normal. 20/50-0.75 sphere equals 20/20. Near vision add plus 2.00 to the above for Jaeger No. 1.

Diagnosis.—Detachment of the retina due to subretinal hemorrhage or tumor.

Course.—The patient was ordered to bed in a dark room on plentiful nourishing diet. His eyes were bandaged, as a precautionary measure to exclude all light, with a black bandage over a white bandage. I put the patient on increasing doses of the saturated solution of potassium iodide, starting to give him to drop three times a day in water. I increased this to 60 drops within a week. Two drops of atropine sulphate 1 per cent. were dropped into the right eye three times daily. This was later increased to every two hours. I enforced absolute quiet. The vision at the beginning of the treatment was 20/200. His range of vision was almost entirely lost. The patient complained of severe pain over the right eye during the entire week. These pains seemed especially severe at night. Examination of the eye on April 19th showed a distinct mass in the lower and inner portion of the globe. This was seen by direct objective examination. Examination with the ophthalmoscope revealed a dark mass. Range of vision was entirely lost and vision reduced to fingers at 2 feet. Tension was minus 1. From April 19th to April 27th the patient's vision gradually increased until it reached 20/100 and he could tell the time of a watch easily. Tension during this time was normal. I made daily examinations of the patient and noticed a gradual disappearance of the tumor during this time until my original detachment could be seen. The mass gradually disappeared so that it was impossible to see it by the objective method. The pain in the head during this time became gradually less, and the patient rested fairly comfortably and only complained of a bad taste in his mouth and a spoiled stomach, which was probably due to the lying on his back and the potassium iodide. During this time the patient complained of severe itching, which annoyed him considerably. I forgot to mention that

the patient was freely purged by Epsom salts during this entire treatment.

There was no circumcorneal injection during any part of the time, the sclera remaining perfectly white; the patient having only a slight catarrhal conjunctivitis. This was relieved by daily applications of 1 per cent solution of silver nitrate. From April 19th to April 27th the patient was taking 80 drops of potassium iodide three times a day. On the 27th of April the patient suffered considerable pain in the right eye and also itching. I was sent for, and upon examination I found a large mass in the lower nasal portion of the globe. This mass had made its appearance over night, as it was not present on the 26th of April, when the patient's vision was 20/100. On the 27th of April his vision had suddenly decreased to fingers at 1 foot. At no time during the entire illness were choroidal vessels seen passing over the tumor.

At the time of my examination on the 27th of April, I pronounced the case one of sarcoma of the chorioid and advised immediate enucleation. This the people objected to without a consultation. Dr. Born was called in consultation, and after a thorough examination fully agreed with my diagnosis, and also advised immediate enucleation. The people not being satisfied still, asked for a third consultation, and Dr. Gruening was sent for, who, after an examination, also agreed with our diagnoses. The patient was immediately sent to the hospital, and on the 28th of April I removed the right eye. The patient after remaining at the hospital for six days went home. During the patient's stay at the hospital his temperature rose suddenly to 102° F. the day following the operation, but upon the administra-

tion of the retina. Socket of the right eye during January, 1908, showed no recurrence of any tumor, the patient being contented and wearing his glass eye. He still has a chronic conjunctivitis, which is being treated by the usual methods.

2047 SEVENTH AVENUE.

## VIVISECTION FROM A STUDENT'S STAND-POINT.\*

BY VICTOR C. PEDERSEN, A. M., M. D.,  
New York.

It is certainly a privilege and an honor to come before you on this occasion, and I sincerely thank you in the name of the Medical Society of the State of New York, which I represent through the Committee on Legislation. I do not utter the slightest reflection upon the purity of motive, the loftiness of aim, or the inspiration of kindness which are behind the antivivisection movement. There are, however, many misrepresentations which physicians hear by word or read in pamphlets which are misleading and unfair, the correction of which is only the just due of those who practise the noble science of vivisection, a term which I use to embrace all forms of experimentation upon animal life. As a matter of fact, the reverse would be a better terminology, as vivisection is only one form of experimentation. As, however, this movement is called an antivivisection movement, one is temporarily compelled to make the term vivisection the more generic of the two terms. The word suffering is used in its broadest sense to mean exactly what its derivation means from *sub*, under, and *fero*, I carry, that is to say, "to undergo," and it therefore applies to any form of animal experimentation with or without the perception of pain. The phrase "perception of pain" means conscious or partially conscious pain in the animal. If we stand in common upon the ground of these definitions, misunderstanding will be impossible.

As a premise for beginning, I may repeat the words of the lady who honored me with the invitation to appear before you, namely: "It is unthinkable that physicians who spend their lives in the service of human suffering and disease should be really guilty of wanton cruelty to animals." Another premise is the fact that pain is perceived less and less as the scale descends from higher to lower warm blooded animals and from warm blooded to cold blooded animals.

The text for my remarks will be furnished by a letter which I have written to the members of the Committees on the Judiciary of the Legislature, in answer to which several have written that it has furnished them with exactly the kind of information which they need in brief form. That part of the letter which concerns my object to-day is as follows:

Physicians are not, as the antivivisectionists believe, indifferent to animal suffering and pain, but they recognize that the amelioration of human suffering and the cure of human diseases are ends which transcend all other considerations. If forty

Sarcoma of the Chorioid

tion of Epsom salts promptly dropped to normal. Aside from a catarrhal conjunctivitis, which usually follows an enucleation, the patient felt perfectly well.

Microscopical examination showed a round cell melanoma-sarcoma. Macroscopical section showed a tumor about the size of a large pea lying in the lower portion of the eyeball between the retina and choroid, and raising the retina considerably. The tumor was round and sharply outlined. It was completely surrounded by a fibrous pigment layer. Above the tumor was a large detachment, beneath which there was considerable exudate. Below the tumor was an exudate also, causing a detachment which was probably a hemorrhage. The tumor was not attached to the optic nerve. The detachment in the lower portion reached nearly to the insertion of the ciliary body. The insertion of the ciliary bodies were exceptionally well preserved in this specimen, the lens showing several opacities and the iris showing its two layers clearly.

In conclusion, I wish to thank Dr. Braun and Dr. Dusen for the painstaking efforts they have taken in the preparation of the many macroscopical sections. The peculiar retrogressive course of the sarcoma at first seemed unusual, as it misled me in feeling that I had a case of hemorrhage which was being absorbed; then suddenly assuming its original size, it plainly showed its malignant character. The gradual improvement of vision from the 17th to the 27th of April also led me to believe I had a case of hemorrhage in the eye with. The absence of choroidal vessels passing over the tumor was another factor, and, lastly, the malignant character, showing itself by its sudden enlargement, accompanied with marked detachment

\* An address before the Medical Society of the State of New York, at the University of the City of New York, on the occasion of the opening of the Medical Society of the State of New York.

years ago, in 1867, when the present law regarding vivisection was passed, vivisection had been forbidden or greatly restricted, the following well known elements of medical knowledge might not to-day be established. I am neither gray haired, bald headed, nor the holder of a professorial appointment. However, having been graduated only ten years ago, I come before you with the standpoint of a student who may perhaps make clear the value of well known vivisection demonstrations. This I trust to do in the simplest and most comprehensible terms. I cannot burden my discourse with scientific detail lest it confuse and weary you. The following, however, are ten points of importance gained for mankind through vivisection:

1. The knowledge of the parts of the brain and spinal cord which govern various parts and functions of the body.

2. The fact that one kidney, the whole spleen, about one third of the intestines, the whole stomach, the womb and the ovaries, as examples, may be removed without death of the individual necessarily ensuing. Nearly every one has had friends or relatives upon whom such operations have been performed successfully.

3. The life sustaining value of normal salt infusions in cases of hæmorrhage, shock, and poisoning.

4. The possibilities of resuscitating the victim of electrical shock by hanging his head downward and performing artificial respiration.

5. The modern treatment of diphtheria with antitoxine serum. Similar sera are now available in other diseases of which typhoid fever and meningitis are types.

6. The amelioration and cure of certain forms of goitre, founded upon observations by Victor Horsley on monkeys many years ago.

7. The comparative safety and dangers of various anæsthetics singly, in sequences, and in combinations.

8. The possibilities of skin grafting in burns and other accidents.

9. The absolute understanding of the mechanics of the circulation, both as to the heart itself as a muscular pump, and as to the bloodvessels as vastly important, elastic and muscular auxiliaries of the heart.

10. Sera as antidotes for snake bites. The British government estimates that 20,000 human beings each year die in India of the cobra bite alone. When the present successful serum shall have been efficiently distributed so that some of these people may be saved, of what possible value will be the guinea pigs and other numerous animals used in developing the serum? This work was begun twelve years ago by Professor Stewart, of Edinburgh.

Modern teaching is founded on the principle that the pupil shall perceive an entity as such, remember and reason from that and not trust to mere memory of printed statements for his supply of knowledge. In illustration, the child of to-day is taught his spelling not from a long list of words selected from a dictionary, but as an act of perception of words as wholes as he reads. Likewise he is taught his natural history not by picture and printed page, but by excursions into the fields and woods with his teacher, where he watches the spider weave its web, the bird

make its nest and rear its young, and the caterpillar eat its special food and pass into the cocoon and then the butterfly stage. Later on, the boy and girl are taught their physics and chemistry in high school and college not as bare printed statements, but as the results of actual experiments in the laboratories. All these things are as they should be, and will in the future produce and train minds probably superior to our own in acumen of perception and validity of reasoning.

Why then should the medical student be denied by law the value of the same kind of instruction in the laboratory through vivisection of animals? The medical man deals with vital forces which cannot be weighed or measured, but whose action can be estimated only by the study of the processes of life. Thus it is that the medical student must make observations upon animals in order to grasp the meaning of scientific facts which cannot possibly be learned from the printed page with equal certainty. In illustration of what I mean and as a matter of personal experience as a student fourteen years ago, let me go back to the headings already enumerated and briefly give you illustrations under each.

1. I learned beyond all possibility of mistaking or doubting the general plan of the principal warm blooded animals as to the control of the brain over the muscles and other organs of the body from the following demonstration: A dog was put under an anæsthetic, and the top of its head removed, thus exposing the brain. While still under the anæsthetic various points of the brain were gently touched with an electric pole carrying a weak current of just strength enough to provoke slight reaction in various parts of the dog's body in turn. After the demonstration the dog, while still under an anæsthetic, was killed. No death could have been more merciful and no means of teaching as adequate, fitting, or lasting. Could this dog possibly have fulfilled the purpose of its being better than by teaching several hundred medical students these all important facts? Does any pet dog, no matter what may be his money value as such, ever contribute to the cause of human knowledge and benefit what this cur did under the anæsthetic followed by death?

2. From animal vivisection it is now known that nearly one third of the intestinal tract may be removed without death. This shows the injustice and unwisdom of requiring the death of all animals vivisected, because after many of these operations effort must be made to keep the animal alive in order to study the effect of the operation upon the economy.

The application of this fact was illustrated in the case of a Dublin boy who was run over by a truck, but who, instead of being allowed to die as he would have been fifteen years ago, underwent an operation for the removal of several feet of his intestines. The child recovered and showed exactly the same differences which are found in animals after such vivisections, namely, that he had to make up for the shortening of his intestines by a vast increase in the amount of his food. This boy may some day be prime minister of England; even if he is not, of what possible importance compared with his life are the distress and the deaths of animals used in developing this point of knowledge?

Primarily through observations upon animals it is now known that one kidney may be removed; and more than that, parts of both kidneys may be sacrificed without death of the subject provided the remaining portions are healthy.

Diseases of the spleen are in some patients now cured by removal of the spleen. Years ago these victims would have been allowed to die unaided. Through animal vivisection it has been learned that the bone marrow becomes the substitute of the spleen in producing the corpuscles of the blood.

The fact that the womb, and the ovaries, may be sacrificed without material harm is a matter of the commonest knowledge to-day, and yet much of the detail of that knowledge was gained at first through operations upon animals.

It may be almost needless to add that all these operations are done under an anæsthetic and the animals treated thereafter exactly as though they were human beings in the effort to make them recover. Most of them are as happy in the laboratories during their recovery as are human beings in the hospitals, and recognize the doctors who work upon them with wags of the tail and laps of the tongue.

3. The fact that the infusion into the veins of 0.6 of a 1 per cent. solution of common salt will sustain life in cases of shock, hæmorrhage, and poisoning, was very largely developed through vivisection. We now know within very reasonable limits of accuracy how much blood by weight an animal may lose and not die, provided the salt solution is quickly substituted for the blood. Through animal observations it has also been proved, and later applied to the human being, that a failing heart in shock may be brought back to life sustaining condition by such infusions. From the same source, namely, vivisection, it has been abundantly established, and later employed for man, that, in some cases of poisoning, blood letting followed by a salt infusion will save life. Remembering the human beings saved by scores each year in the civilized world by these means, of what significance are the animals which underwent vivisection, either with or without unavoidable perception of pain, to prove these things?

In illustration I remember a man who died after an amputation of both legs due to a railway accident eleven years ago when I was an interne in one of our large hospitals. Two years ago I saw a woman survive the same operation because with better knowledge she was first gently infused until her heart improved and then after just enough anæsthetic had been given to stop pain, and no more, the amputation was quickly done. Part of this skill was gained from vivisection.

4. From time to time one hears of cases of electrical shock in the human being followed by recovery due to inverting the patient and giving artificial respiration and stimulation. The fact that within certain limits electrical shock need not necessarily be followed by death was first demonstrated upon animals. Are the lives of the animals which suffered, or the animal persons thus underwent, anything in comparison with the human being of to-day who may be saved?

5. In the days before the diphtheritic antitoxine

had been developed nearly eighty per cent. of all children, victims of the disease, died. Mortality has been reduced now to less than ten per cent., if the children be seen early, the disease correctly diagnosed, and the antitoxine quickly administered. Yet this serum was produced at the cost of some animal suffering in various creatures until finally the horse was found to be the best source of the serum. Can we stop to consider this loss of animals when we remember the safety of our own children thus cured? Compare, for example, two cases within my own experience. In 1873 I had a cousin die of diphtheria of the larynx in forty-eight hours, just as she was reaching young womanhood. Two years ago I saved the infant son of a comrade, the victim of diphtheria of the larynx, by a timely injection of antitoxine. In less than four hours after receiving it the child's condition began to improve; he passed a quiet night for the first time in several days, and, in two days, instead of being dead, was practically symptom free. It is needless, of course, to say that in this baby no membrane had as yet formed, but it was sick enough to get up on all fours at night to breathe, at times also ran a high temperature, and had a poisoned look.

The Board of Health in 1907 reports 15,276 cases of diphtheria. If eighty per cent. of these had been lost, the deaths would have been 12,221 as against the actual number of 1,740. This fact is without reference to the violent epidemic which would have ensued but for the preventive value of serum treatment. No distinction is made in the number actually lost due to cases complicated with scarlet fever. Bright's disease of the kidneys, pneumonia, and the like, and last and most important, due to ignorance and neglect on the part of parents, whereby serum was omitted or given too late.

6. Goitre or enlargement of the thyroid gland was first explained by Victor Horsley, about twenty years ago, through vivisection of monkeys in England. His results have made it possible to rescue from a life of idiocy and uselessness children who are born without a thyroid, known technically as cretins. They are dull of eye, with at best slow minds, or practically deprived of intellect, thick tongued, sallow, heavy skinned, and on the whole, revolting and disgusting in appearance. Thyroid extract given to these individuals will commonly work miracles. I remember as a student seeing a baby changed in eight months from a useless and disgusting specimen to a playful and interesting child by just this form of treatment.

Another form of goitre is characterized by rapidity of the heart, causing breathlessness, extreme nervousness, and a terrifying prominence of the eyes. Horsley's observations have also served to demonstrate the best way of returning these unfortunates to perfect or reasonable health.

In speaking of goitre before our class Professor Starr said that vivisection needed no apology; if it did, the experiments of Victor Horsley as to goitre would for all time be the only apology necessary. Applause, in which our ladies would have joined if you had been present, followed these remarks upon our seeing the human beings who proved the truth of this assertion by their cures and improvements.

7. In general terms it is known that ether and chloroform are the best anesthetics we have, yet animal experimentation involving the death and suffering of some animals has shown that chloroform depreciates the value of the circulation from ten to thirty per cent., a fact which must be reckoned with in choosing between the two at all times. Yet, on the other hand, it has reasonably been proved, similarly with sacrifice of animals, that if the fumes of these anesthetics are given warm the dangers are almost divided by two. When after years of observation in the human being these facts become thoroughly recognized, where will the animal loss stand in summing up the usefulness of the results obtained?

8. Skin grafting is now a matter of common knowledge, yet some of its principles are born of the suffering imposed on animals, proving the fact that in certain instances living parts of the body may be rapidly transmuted to other parts and survive.

9. The actual mechanics of the circulation, as to the heart itself as a muscular pump were shown by the following experiment before about five hundred medical students in college when I was there.

A calf was thoroughly anesthetized and its heart widely exposed through the chest wall. While the animal was kept alive and breathing by artificial means, it was possible to watch the course of the blood with great accuracy as it flowed into the heart and out again.

Through this animal demonstration under an anæsthetic, the medical student of to-day is shown how the blood, returning to the heart from the system at large and from the lungs, rushes into the upper part of the heart, technically called the auricles, passes, by a contraction of both auricles together, into the lower or heavier part of the heart called the ventricles, and by contraction of these in unison into the lungs from the right ventricle for purification and from the left ventricle into the main blood channels for nourishment of the body. This demonstration is so graphic that no human being of ordinary perception and understanding can ever after it have any confusion in his mind as to what the heart is doing when he listens to it in the chest of the patient. The characteristics of change of blood pressure by contraction and dilation of the bloodvessels and many other wonderful features of the circulation of the blood are also shown in a similar way. Since all these matters of knowledge are for later practical application in the treatment of disease among human beings, of what possible matter is it whether a certain number of animals perceived some pain perhaps, or even in many instances lost their lives? All the animals used for such purposes are under anesthetics, and after the lesson is over are destroyed before they come out of the anæsthetic. To deny the right of the medical student as he comes and goes generation after generation to see these same demonstrations repeated would be like a professor stating to new classes of mechanical engineers something like the following: "This is a complicated and high speed engine; ten years ago my class took it apart and put it together again in working order. These men have since then become the leading engineers of the coun-

try; you cannot, however, take the engine apart, but will have to accept on faith what we learned about it at that time."

There is certainly no cruelty whatever, directly or indirectly, in employing animals for such purposes. Each medical student is entitled to know from his own personal observation and perceptions exactly what these processes of life mean, exactly as each student is entitled by actual experiment to know the facts of other sciences, such as chemistry, physics, electricity, and the like. To deny to medical students this right would be stepping backward in their instruction thirty or forty years.

Which of the following two calves fulfils in the higher degree the purpose of its being for man's benefit—one which is slaughtered, its body consumed as food, its skin as shoes, its skeleton ground up for chicken food, and its entrails employed as fertilizer, or a calf used for such as the foregoing demonstration before five hundred medical students who may in their lives through the knowledge thus given easily benefit one hundred thousand human beings? The skin, flesh, skeleton, and entrails of the second calf could well be employed exactly as those of the first, or its skeleton might be set up in a museum of comparative anatomy to show the beauty and the order of the animal kingdom, to laymen, medical, and veterinary students alike.

We have already spoken of antidiphtheritic serum. Other important sera have been developed and applied as follows. They are all developed from painstaking animal experimentation, sometimes with suffering, usually without perception of pain to the animals. I am indebted to Dr. Simon Flexner, chief of the Rockefeller Institute of Medical Research, for the following authentic list of sera:

(a) Sera of wide application and great success in diphtheria, dysentery, tetanus (as a preventative measure), and antivenin (employed with great results against the cobra bite).

(b) Sera partially successful are employed in meningitis, scarlet fever, typhoid fever, and against the rattlesnake bite in animals. Cases of rattlesnake bite in human beings are rather rare, and no observations are at present recorded.

(c) Sera that are successful in treating animal diseases are now available in anthrax, rinderpest (a tropical disease common in cattle), and hog cholera.

(d) Protective inoculation of animals is now successfully carried on in tuberculosis by serum obtained from the human tubercle bacillus. Also in anthrax, blackleg (quarter evil), and chicken cholera. Thus is man handing back to his bovine friends (cattle) protection from tuberculosis by inoculation. This is the same order of wonderful phenomena as is vaccination itself in smallpox from cow to man. Permit me to digress one moment to say that, if vaccination needed any argument to support and warrant it, that argument is found in the medical books written at the time Jenner made his wonderful discovery, that is, about 1790. Statements are met with like the following: Three quarters of the entire population of London have had the smallpox. If London at this time was a city of four hundred thousand, three hundred thousand of these gave obvious proof of having had the disease, a statement which does not include any reference to the deaths

from smallpox at that time. Last year in New York City the Board of Health reported fifty-eight cases in a population of fully three million five hundred thousand or four million during 1907. In Germany, where vaccination is absolutely compulsory, the disease is almost extinct, excepting in the seaports, where occasional cases arrive. Again in the Franco-Prussian War, the French army, which had no compulsory vaccination, lost by death from smallpox vastly more soldiers than were even stricken in the German army, the ratio being given by some authorities as more than 10 to 1. In the German army all were vaccinated.

(e) Sera for establishing diagnosis in animals are now available in tuberculosis and glanders respectively called tuberculin and mallein.

(f) Among drugs of remarkable value proved by animal experimentation is atoxyl, which is a wonderful means of curing African sleeping sickness, of which doubtless some of you have read. The value of this, too, was developed by animal experimentation.

(g) Rather satisfactory results have also been obtained up to the present in the matter of cancer experiments in rats and mice. When the day comes for fully developed means of combatting this dreadful scourge in the human being, which one of you will stand up and object to the possible suffering of the animals in developing that truly miraculous product—because it will be truly miraculous?

To the foregoing ten illustrations of actual and lasting benefits conferred on man by vivisection, I could add many others, but time forbids, moreover these ten elements of human knowledge thus gained and proved from vivisection, are fully ample for our purposes.

These remarkable and more or less familiar illustrations of some of the results of well balanced vivisection will prove my contention at the outset, that this science is not a disgusting but an ennobling sphere of human study.

A few words should be added as to the apparatuses pictured in the lay press which are used in vivisection. Kindly bear distinctly in mind the fact that animals' backs are round and will not rest motionless upon a flat table while they are under anesthetics. It is therefore necessary to fix two boards at right angles to each other to make a gutter like pocket in which the rounded back of the animal will not shift. Motion may mean failure of the whole operation, and sacrifice of another animal.

Straps and other devices are required to keep the paws of the animals away from the sterilized hands and instruments. Similar methods are necessary even in human beings under anesthetics, because as unconsciousness ensues frequently the arms and the legs get into the surgeon's way and greatly impede rapidly, precision, and surgical cleanliness of the work. In man and in animals this apparatus is beneficial, merciful, and well intentioned, and not harmful, cruel, and malicious, as the pictures are meant to imply.

For example, I saw one picture of a dog with its mouth gagged wide open by an apparatus. No screw or bar bore anywhere upon the dog except that across its mouth and teeth. Had dogs the same tooth plan as horses, namely, had they a space be-

tween the grinding teeth behind and the biting teeth in front, this bar would have been resting in that space and the dog could have closed its mouth. This apparatus is no more an instrument of torture than are the mouth gags employed in man, pictures of which almost made me faint when a young man contemplating the study of medicine and caused me to doubt my fitness, until I realized that real sympathy lies not in the fainting but in helping and in doing.

Let us turn now to the proposed Acts before our Legislature limiting vivisection, with a brief criticism of their shortcomings.

First the Cobb-Johnston Bill. It may very well work a hardship to require that vivisection shall be done only in certain institutions. For example, a friend of mine practising in a mining town in Pennsylvania saw that miners who were the victims of crushing, scalds, and other accidents, very frequently died if put under a general anæsthetic for treatment. The thought occurred to this medical genius that perhaps a local anæsthetic, of which cocaine is the type, injected into the spinal canal might permit life to continue during the early treatment of the case. He therefore took thirteen dogs and subjected them to various injuries similar to those suffered by the miners. The question may arise, why did he not anæsthetize them? This was because he had to repeat in the dogs the same conditions found in the miners. The miners were not under an anæsthetic when injured, therefore the dogs should not be. The miners died under anesthetics while being treated; it was therefore necessary to see how dogs would act under the two methods of anesthesia. He proved that the dogs, too, died under a general anæsthetic, but afterward found that, if a local anæsthetic was employed, many that previously would have died, lived. In the same article in which he published these observations he also published the reports of several cases of miners who, under the influence of cocaine thus used, did not die, but lived. Of what value were these thirteen dogs in the face of these facts? If this doctor had been compelled to go to New York or Philadelphia to carry out his experiments they might never have been performed, for perhaps he could not have afforded to leave his practice for the purpose.

It is unfair to withdraw from the physician a decision as to whether or not an anæsthetic is desirable. The whole point of the observation may rest upon not giving an anæsthetic, as for example in the foregoing instance. If we are to unravel the mysteries of the nervous system we must be allowed free hands in deciding the best methods for reaching the truth.

It would prove a hardship to require that animals after the operation or experiment shall be killed, because the result of the study may rest absolutely upon whether or not the animal may be kept alive. For example, consider the operations on various organs, such as removal of the kidneys and the like, followed by survival of the animal in good health.

It will deprive the modern medical student of his best source of knowledge to require that facts already known shall not be demonstrated again to each class by animal experiment. It would be equally unwise to say that all chemical laboratory in-

vestigations shall cease so far as the proof of facts already established is concerned. Knowledge cannot possibly be gained so wisely and well as by seeing real, natural processes in the course of their action. This necessarily includes the vital forces of animal life with which the doctor has to deal throughout his practice. As you have perhaps noted already, one or a very few animals a year are usually enough for a given demonstration in each medical school.

Physicians are entitled to demand that their scientific researches shall not be inspected by laymen and shall not be inspected under the direction of lay societies, perhaps largely composed of misinformed and hostile persons. In other lines of human activity the similar demand is made and appropriately conceded, namely: The boilers of our engines and factories are inspected not by layman but by competent engineers. Our electrical installations are inspected not by laymen but by suitably trained electrical engineers. To impose upon medical men any new principle is unwise, unfair, and contrary to human experience through ages of civilization.

I doubt very much whether any of you present would honestly and honorably consider herself competent to pass upon the validity of any animal experiment, either from the standpoint of its pain giving or its results, even though she might stand before the law as the accredited representative of some humane society. Such a requirement in this law is against human experience in other lines of human knowledge, and no new principle may fairly be applied to the form of human knowledge which we are discussing.

Next, the compulsion of annual reports is another objectionable requirement whereby scientific research may very well be greatly hampered, interrupted, and interfered with.

Certainly nothing but good to humanity has in the past come from vivisection as conducted under the present laws, and in virtue of these facts there is truthfully no need of any new law. The Davis-Lee Bill also imposes a number of injurious, vexatious, and needless limitations upon the work of men whose only idea is the amelioration of mankind.

The allegation is made that a similar law is of advantage in England. Permit me to state the following facts: This law has in the past driven Sir T. Lauder Brunton from London to Paris to perform experiments. Upon Brunton's work depends much of our knowledge of the action of modern drugs obtained by the improved methods of modern chemistry. He is one of the greatest observers of drug action in the world. Is it not hardship and injustice that a man of his nobility of purpose should ever have been driven out of his country in order to perform experiments to the results of which humanity is honestly entitled?

In closing let me allude to an incident which has created a good deal of comment, namely, a memorial erected in Battersea Park, London, by Stephen Coleridge. The monument caused bitter hostility among vivisectors, resulting in a riot, according to *Life*, which also states that the inscription reads: "In memory of the brown terrier dog done to

death in the laboratory of University College in February, 1903, after having endured vivisection extending over two months and having been handed over from one vivisector to another until death came to his release. Also in memory of the 232 dogs vivisected in the same place during the year 1902. Men and women of England, how long shall these things be?"

Part of the fallacy of this monument lies in the fact that many of these experiments upon this dog must have been of a very simple nature and without pain. Time does not permit me to illustrate some of the valuable observations for teaching students which may well have been carried out upon this dog. Instead, however, of a riot ensuing, how much better it would have been if another monument had been erected, a duplicate of the first, but surmounted by the statue of an infant, and bearing the following inscription:

"Sacred to the memory of the countless children of tender years who in the past died of diphtheria before the noble science of vivisection had given to men the knowledge of immunity, and of the serum treatment of diphtheria, through observations on animals. Sacred also to the memory of other human beings who have died of diseases whose cure will one day be discovered through vivisection. Sacred also to the memory of the animals who in fulfilling their purpose of existence in the service of man have given up their lives for the establishment of important facts in medical knowledge. And finally, sacred to the honor of the noble men who with singular honesty of purpose in the past and present have, and in the future will, through well purposed animal vivisection, bring to human knowledge the present undiscovered mysteries of life."

In the past much that is incalculably useful has been accomplished, in the present much that is of inestimable blessing is being attained, and in the future more still will be given to man in knowledge gained through purposeful vivisection. It behooves the misinformed layman to be thankful and appreciative, and not ungrateful and obstructive.

45 WEST NINTH STREET.

#### MALARIA IN GREECE.

By A. ROSE, M. D.,  
New York.

At the annual international competition at the Academy of Medicine of Paris the prize, a silver medal, was awarded this year to Dr. John P. Cardamatis, of Athens, Greece, for his work *On Elenosia (Malaria) in Athens*. In this monograph is given the history of the disease in Athens from the prehistoric times to the present day.

Dr. Cardamatis is the founder of a *sylogos* which has for its object to combat malaria in Greece, and stands under the protection of the king of the Hellenes. Our distinguished Greek colleague honored me by sending me the report of his *sylogos*, a large octavo volume of 653 pages for the years 1905 and 1906, written in Greek by him and Pro-

ΥΠΕΡ ΤΗΣ ΕΛΕΝΟΣΙΑΣ (MALARIA) ΕΝ ΑΘΗΝΑΙΣ ΚΑΙ ΤΗΣ ΠΡΟΦΥΛΑΞΕΩΣ ΑΥΤΗΣ ΣΥΛΛΟΓΟΣ. ΕΚΔΟΣΕΙΣ ΤΗΣ ΕΛΛΗΝΙΚΗΣ ΚΑΡΔΑΜΑΤΙΣ, Γ. ΣΑΒΒΗΝΑ ΚΑΙ ΛΕΩΝΙΔΗ. Π. ΚΑΡΔΑΜΑΤΙΣ ΕΤΕΡΟ ΚΑΙΝΟΤΟΜΟΝ ΚΑΙ ΔΕΥΤΕΡΟΝ, ΕΤ' ΑΘΗΝΑΙΣ, 1907.

fessor C. G. Sabba, of the University of Athens. Presuming that much of the contents will be of interest and value to American physicians, I will give an extract of the same.

According to the statistics in this report Greece is perhaps of all countries in the world the most afflicted with malaria. This is also the opinion of Ross, who has studied the disease in East India and Africa, but it is contrary to Celli's view who gives to Italy this unfortunate first place.

Malaria has been prevailing in Greece from the remotest period all through its entire history. In the Orpheus poems, assumed to have been written about the year 1000 B. C., the different types of malaria are most exactly described. The description of the disease by Hippocrates is well known to all who are familiar with history of medicine. The writers of the classical period in general describe its existence during this time, only from the epoch of the downfall of ancient Greece exact informations are lacking. Under Turkish rule cultivation of the soil was neglected in Greece, and mostly so during the War of Independence, which lasted seven years. The little Greek nation had fought until her land had been devastated and her race decimated. The sword, famine, and disease had reduced the population to about one third of its original number, and this third to a state of most complete destitution. Vegetation was destroyed, especially the forests, by fire. On account of the bareness of the mountains after the destruction of their forests, torrents of water would overflow the fields and become converted into marshes, the favored places for the development of mosquitoes. After the war was over, order began to be restored, the population increased again, and the cultivation of the soil was taken up anew, especially drainage of marshes. But how much is left to be done yet will be seen from the description of conditions existing at the present time.

Official statistics about the spread of malaria in Greece exist only since the year 1899, and even these are as yet confined to the statistics of the board of health of the twelve larger cities of Greece, of those which have a population of ten thousand and more. From these statistics we learn that during the period from 1899 to 1906, that is in eight years, there were 2,174 deaths in the large cities from different forms of malaria, a yearly rate of 272. From ten thousand city inhabitants in Greece 9.7 die from malaria; in 100 deaths 4.36 are due to malaria. The details of these statistics regarding the months of the year, the ages of the deceased, the distribution over valleys, the immunity of the altitudes over 800 metres, and all the details which we expect to find in official statistics are given.

While in Greece, according to the investigation of the syllogos, among 100,000 inhabitants 12848 are afflicted with malaria, the number in Italy is only 4088 among 100,000. While the Italian population of thirty-four millions consumes yearly twenty thousand kilogrammes of quinine, the Greek population of two and one half millions (eleven times less than the Italian) consumes five to eleven thousand kilogrammes.

There are one million acres of marshes in Greece. A great deal of drainage has been done by two companies, an English and a Greek company.

The syllogos, similar to the one established in Italy, was formed by Dr. Cardamatis in the year 1905, who commenced his work on May 4, 1905. It has the hearty support of distinguished physicians, clergymen, politicians, in fact of the whole population; has been recognized by royal decree and stands, as mentioned, under the special protection of the king, who takes personally the warmest interest in the vital question here involved, and, as we shall see, promotes in many ways the work of this patriotic society.

One of its first objects is to make popular the information about malaria among all classes in all cities and villages of Greece. To this end committees have been formed which are headed by the highest in rank, the archbishops, mayors, physicians of distinction, in fact all influential men. The next object of these committees is to study all concerning malaria in their respective districts, the existence of marshes, the means and ways for the drainage of such marshes, to destroy mosquitoes, to provide quinine either free or at the smallest price for the poor, as therapeutical as well as prophylactical measure, to elicit the interest of the priests, the municipal authorities, the physicians, the teachers, to collect money destined to promote the purpose of the syllogos. In order to facilitate this work, the syllogos has issued brief instructions, printed in form of hand bills similar to those published in Italy, and distributed them everywhere. They were sent out by the Department of Public Instruction to the teachers of the public schools with the request to propagate the contents through the pupils to the families. In order that the knowledge about malaria becomes more clear among the population, pictures of plasmodia, of the development of the mosquito, and other illustrations about the genesis of the fever have been added. These illustrations are distributed now to be hung on the walls not only in all public schools, but also in the shops, the railway stations, the coffee houses, etc. It is contemplated also to put postal cards with illustrations concerning malaria into circulation, and finally a kind of decalogue corresponding with the Italian malarian decalogue, commandments of precaution against malaria. It is intended to give discussions with demonstrations by means of the stereopticon not only in medical societies, but also for teachers and the general public in the cities. This has been considered as promising to be an effective mission for physicians who will go from place to place, welcomed by the country practitioners, who will learn the most advanced modern views.

The syllogos has addressed himself privately to every one of the wealthy landlords, sending them instructions about the measures of drainage of the little marshes in their states.

The daily press and the literary magazines have greatly contributed in disseminating the ideas of the syllogos by publishing articles and pictures relating to precautions against malaria.

Simultaneously with popularizing all these measures the syllogos collected information about location of marshes everywhere and to make maps on which they were marked.

For the destruction of the larvae of the miasma olive oil, petroleum, and lime are recommended. Olive oil is abundant and even cheaper than petre-

leum; it can be used either alone or mixed with the very popular oil of turpentine. A greater amount of olive oil is required to cover a certain surface of water, but on the other hand it is conserved for a longer time than petroleum, which latter is quickly evaporated. A special advantage in Greece is that olive oil is always on hand, every peasant has it in the home, and a further advantage is that it has no odor and does not make the water unfit for various purposes in the house, for the animals to drink from, and for watering the garden. Besides it has to be taken into consideration in Greece that extensive distribution of petroleum is dangerous where forests are near, and this danger must not be overlooked on account of the great dryness which exists in Greece in summertime, the many dry bushes and that kind of tree, the pine tree, which is especially combustible.

As the syllogos has under consideration the drainage of the great marshes, the surface of which amounts to about a million acres, as told, and which is most difficult and requires long time and excessive costs which the budget of the government can bear only gradually, the members directed their attention to the drainage of the little marshes in the neighborhood of cities and villages, the drainage of which is easy by means of the well known methods. To this end the syllogos recommended the drainage of the little marshes, asking the government to pass laws forcing the proprietors of every estate to make the necessary drainage, public lands to be drained by funds provided in the state budget or the communities, or to oblige inhabitants to work personally. The government is also asked to form brigades for special duty, corresponding to the Ross mosquito brigade.

#### CAMMIDGE REACTION IN PANCREATIC DISEASE, WITH NOTES OF A CASE.

By G. A. FRIEDMAN, M. D.,  
New York,

Visiting Physician to Yorkville Hospital and to the German Polyclinic.

While our knowledge of the physiology and pathology of the pancreas has greatly increased during the past twenty-five years, no corresponding advance has been made in the symptomatology or the diagnosis of the lesions to which the gland is subjected. Nearly thirty-three years ago Friedreich wrote: "No single symptom which may occur in pancreatic disease is pathognomonic, and even the combination of several symptoms does not always lead to a positive diagnosis." Little can be found to aid one in diagnosis in either textbooks or monographs written since then. Even in diseases of the head of the pancreas, where the signs are more marked, it is often hard to exclude affections of other organs with similar signs, as, for instance, gallstones, cancer of the papilla of Vater. In most of the cases where a correct diagnosis has been made, this was done by the process of exclusion. The character of icterus described by many authors

as being very deep in pancreatic lesions will hardly help any one to make his diagnosis certain, as the so called deep icterus may be present in affections of the biliary tract just as well.

Should a mass be palpated in the supposed pancreatic region, which occurrence is very rare, its proper connection with the gland is not always discernible. Pain in pancreatic affections is one of the most unreliable symptoms on which to base our conclusions. Visible fat in the stools, marked amount of neutral fat crystals under the microscope (steatorrhea), the presence of striated muscle fibres in the stool (azotorrhea), these are the findings which may suggest a pancreatic lesion. This becomes obvious by taking into consideration the fact that the pancreas produces ferments for the purpose of regulating normal digestion. In a diffuse affection of the gland the power of secretion is either reduced to a minimum or abolished altogether, the latter happening very seldom. In obstruction of the duct of Wirsung from certain causes, the flow of pancreatic juice is dammed off.

In such instances the reaction of Sahli may yield negative results. This test is based upon the observation of Sahli that salol, a compound ether of salicylic acid, is decomposed through the action of pancreatic juice in the small intestines into phenol and salicylic acid. A violet color is produced by adding a small amount of ferric chlorid solution to the urine, due to the presence of salicylic acid eliminated through the kidneys.

In assuming a normal motility of the stomach, or nearly so, the pancreatic juice had not entered the bowel if, after taking 2 grammes of salol, the urine of the patient does not show the above mentioned reaction after a lapse of twenty-four to forty-eight hours.

Of greater importance is the quantitative estimation of nonutilized fat and nitrogen in the stool. For this purpose it will sometimes suffice to place the patient on a mixed diet. But to obtain correct results a standard diet, as the one proposed by Schmidt, must be resorted to for at least three days, viz.: In the morning—One glass cocoa (prepared from  $\frac{1}{2}$  of an ounce cacao powder,  $\frac{1}{4}$  of an ounce sugar, 2 ounces milk, 6 ounces water), and 2 ounces zwieback. In the forenoon—Two glasses of oatmeal gruel (from  $1\frac{1}{2}$  ounce of oatmeal,  $\frac{1}{3}$  ounce butter,  $\frac{2}{3}$  ounce milk, 10 ounces water, and one egg strained). At noon—4 ounces chopped beef (raw weight), broiled rare with  $\frac{2}{3}$  ounce butter. In addition, 8 ounces potato broth (made of 6 ounces mashed potatoes,  $3\frac{1}{2}$  ounces milk, and  $\frac{1}{2}$  ounce butter). In the afternoon—As in the morning. In the evening—As in the forenoon.

With the first breakfast a five grain carmin capsule should be given to the patient, for the purpose of demarcating the stool resulting exclusively from this test diet. The first red colored stool is used for the quantitative analysis. This method, though correct, is inconvenient for the physician, as definite results cannot be obtained before three days.

Normally, according to Schmidt, the percentage of fat in the dried faeces ranges between 21.5 and 26.61. If we find a percentage of 40 or over, a pancreatic lesion may be suspected. A high per-

\*Presented at the East Side Physicians' Association, with demonstration of a case. *Proceedings*, 1913, p. 38.

centage of nonutilized nitrogen may also be found in affections of the pancreas.

The presence of sugar in pancreatic disease is very rare. This is a fact acknowledged by most of the authors. According to the studies of Weichselbaum, Stangel, and Opie, mellituria is apt to be found only when a considerable number of the islands of Langerhans are affected. Hence it is obvious that pancreatic lesion may be present without glycosuria.

As the object of this paper is not to give all signs which may help to form a positive diagnosis in pancreatic disease, we shall make a short critical review of only those more prominent ones as already pointed out.

Let us assume a given case, in which steatorrhœa has been noted. The history and present findings exclude tuberculosis of the intestines, tuberculosis of mesenteric glands, and a retroperitoneal tumor (which may press upon a portion of the small intestine and interfere with the absorption of fat). In this case, a pancreatic lesion could be diagnosed if icterus is absent.

The presence of fatty stool, if noted, can also be due to obstructive jaundice, without pancreatic affection, since we know from Schmidt that 50 per cent. of nonutilized fat may be found in the feces of patients with affection of the biliary tract. Furthermore, Müller stated that when bile was excluded from the intestine, 52.2 to 75 per cent. of the fat contained in food was passed unabsorbed, as against 7 to 11 per cent. (the latter being the normal amount, according to his investigations).

Further studies showed that in the stools of pancreatic patients there is a predominance of neutral fat over fatty acids. The reverse condition holds true for biliary obstruction without changes in the gland. Mayo Robson, in his work, came to the same conclusions. But there are instances of pancreatic lesion where the ratio between neutral fat and fatty acids is not so conclusive.

The next prominent sign in pancreatic lesions is azotorrhœa. If we find undigested striated muscle fibres in a large number of microscopical preparations, we must first be certain that the motility of the stomach and intestines is normal. Since, in the derangement of the stomach, atonic or hyperstalsis of the bowels is present, the azotorrhœa may point to these conditions.

On the other hand, a number of cases are on record where neither steatorrhœa nor azotorrhœa were present, and nevertheless pancreatic lesions were found at autopsy or operation.

These possibilities are explicable by recalling a few facts concerning the physiology and pathology of the gland. We know that the pancreatic juice may enter into the duodenum by way of the duct of Santorini when the duct of Wirsung had been occluded by calculi or inflammatory swelling; hence pancreatic lesion may be present without disturbance in the flow of pancreatic juice. Even if the duct of Santorini be deficient or occluded from the same causes, an accessory pancreas may furnish its ferments to the bowels.

Assuming by a concurrence of favorable conditions that a positive diagnosis of pancreatic lesion

had been arrived at, still we are sometimes at a loss to determine the nature of the same. It is of little importance for the patient whether we are unable to diagnose his condition in acute pancreatitis. The onset in this affection is acute, even fulminant. In spite of the fact that the symptom, pain, can be referred to different abdominal organs, yet the physician ought to recognize the condition as not a medical one, and the patient ought to be turned over to the surgeon with a diagnosis of gallstones, abscess of the liver, acute intestinal obstruction, appendicitis, etc. An exploratory laparotomy will be performed, and the patient will often be saved. A cyst of the pancreas may be diagnosed previously to an operation. Should this not be the case, however, exploration of the patient on account of an indefinite abdominal tumor will often clear up the situation. In the same manner a patient with pancreatic calculi may be helped by an operation, following exploratory incision.

Entirely different is the question with two affections of the pancreas—chronic or subacute pancreatitis and carcinoma of the gland. We are not only unable to distinguish these two conditions during life, but we are often unable to do so even after a laparotomy. Should a microscopical examination of an extirpated piece of the pancreas show evidence of chronic pancreatitis, still we are not absolutely certain, since an examination of the whole gland had not been made. How desirable it would be to have means of making a positive diagnosis of one or the other condition!

If we could exclude carcinoma, and if medicinal treatment for chronic pancreatitis should have failed, we then all the more have to refer our patient to the surgeon, as the results of the operation in this condition are very encouraging indeed (about 4 per cent. mortality, according to statistics of Robson). Sometimes a simple exploratory incision may suffice for recovery, as in a case quoted by Chambers and Friedenwald.

If a malignant growth of the pancreas is present, the condition should mean a *noli me tangere* to the surgeon.

In this way we arrive at the reaction of Cambridge, or pancreatic reaction in the urine. Thanks to this author (Cambridge), we are not only able to confirm our diagnosis in suspected pancreatic lesion, but also are able to distinguish carcinoma from inflammatory processes.

As the basis for his reaction was the condition of fat necrosis, a brief description of this pathological phenomenon should be given. Ponfik first described the process of fat necrosis in the bone marrow. After him, Balser observed about the pancreas of a number of bodies small, opaque, white areas, often surrounded by a hemorrhagic zone. These areas were shown to be composed in great part of necrotic fat cells.

Fitz offered the suggestion that fat necrosis is consequent upon a lesion of the pancreas, and supported this conclusion by numerous instances in which the two conditions had been associated. Though the condition is met with in the majority of cases in acute hemorrhagic and gangrenous pancreatitis, the process of fat necrosis has also been

detected in other lesions of the pancreas microscopically, when no evidence of the same had been noted by gross appearance of the gland.

Cammidge looks upon punctate hemorrhages, which frequently occur in lesions of the gland in the absence of necrosis, as an early stage of this condition. According to him, similar but less marked changes may be present in all instances of pancreatic lesion. Sometimes the process of fat necrosis may be overlooked by the operating surgeon or at the autopsy table.

It has been shown by Langerhaus, Flexner, and others that the changes taking place within the fat cells of the gland or the abdominal viscera are associated with the splitting up of the fat molecule into fatty acids and glycerin, through the fermentative action of pancreatic juice. Fatty acids are deposited as needle like crystals within the cell, which has lost its nucleus and is necrotic, while the soluble glycerin is absorbed by the blood. The fatty acids soon combine with the calcium of the blood plasma to form salts, which remain in the necrotic foci.

At first Cammidge experimented with the blood of patients affected with various diseases of the pancreas. As this method did not seem to him to be practicable, on account of the small amount of blood available at bedside, he turned his attention to the urine.

Notwithstanding the fact that glycerin brought into circulation is oxydized by the elimination of carbon dioxide, yet Cattilón showed that 50 per cent. or 60 per cent. of the same can be detected in the urine of dogs who had been given this per mouth.

Cammidge is certain that even higher percentages may be obtained in urines of pancreatic patients, since, in the latter, the process of oxidation is diminished.

It is a well known fact that glycerin, on being boiled with nitric acid, gives rise to glycerol, which can be recognized by the osazone which forms with phenylhydrazin. Experience showed him very soon that clearer preparations could be obtained with hydrochloric acid. Finally, two reactions were worked out by Cammidge, called "A" reaction, and a distinctive reaction, called "B."

*The "A" Reaction.*—The specimen of urine to be examined is filtered. 10 c.c. of the filtrate are poured into a small flask. 1 c.c. of hydrochloric acid (sp. gr. 1.16) is added and a funnel placed in the neck to act as a condenser. The flask is set up on a sand bath and gently boiled for five to ten minutes after the first sign of ebullition is detected. The flask is afterward cooled in running water. After cooling, the mixture is filtered. To 5 c.c. of the filtrate is added 5 c.c. of distilled water. The excess of acid is now neutralized by slowly adding 4 grammes of lead carbonate, and, after standing for a few minutes to allow the completion of the reaction, the urine is filtered through a well moistened filter paper and the flask is washed out with 5 c.c. of distilled water on to the filter. To the clear filtrate are now added 2 grammes of powdered sodium acetate and 0.75 grammes of phenylhydrazin hydrochloride, and the mixture is boiled from three to four minutes on the sand bath. The hot fluid is then poured into a test tube and allowed to cool undisturbed. After the lapse of a period varying

with the severity of the case from one to twenty-four hours, a more or less flocculent yellow deposit is found at the bottom of the tube. The precipitate, when examined under the microscope, is found to consist of sheaves and rosettes of golden yellow crystals.

Sugar when present must be freed by fermentation and subsequent heating for removal of the formed alcohol. Albumin is removed by acetic acid and boiling.

When the "A" reaction is positive the "B" reaction has to be made.

*The "B" Reaction.*—20 c.c. of filtered urine is mixed with 10 c.c. of saturated solution of perchloride of mercury. Carefully filtered and after standing a few minutes, to 10 c.c. of the filtrate is added 1 c.c. of strong hydrochloric acid. The mixture is then boiled for ten minutes on a sand bath, and subsequently to 5 c.c. of the urine is added 10 c.c. distilled water. After cooling, it is neutralized with 4 grammes of lead carbonate. The remaining stages of the reaction are like those of the "A" reaction.

The "B" reaction is a differential one, based upon the observation of Cammidge that in inflammatory conditions of the pancreas the crystals obtained are destroyed by the action of perchloride of mercury. A large number of examinations showed Cammidge that the crystals in malignant disease are broader and coarser, while in inflammatory processes they are smooth and slender. The solubility of the crystals in a 33 per cent. solution of sulphuric acid is different according to the nature of the affection. The crystals obtained from a specimen of acute pancreatitis are soluble in from one-half to one-fourth of a minute; in chronic pancreatitis, in from one-half to two minutes; in carcinoma, in from three to five minutes and longer. In pneumonia and in adenitis crystals have been noted which were soluble in one minute.

Negative results with these reactions have been obtained by Cammidge and also Robson in normal urines in icterus catarrhalis, in gallstones without pancreatitis, in ulceration of the stomach, and in various other conditions.

In support of the pancreatic reaction of Cammidge may be added that Felix Eichler has lately experimentally produced acute pancreatitis in three dogs, and in the urine of all he found the characteristic crystals of this condition, while in the urinary specimens of dogs in good health the results were negative.

The following cases well illustrate the diagnostic value of the pancreatic reaction in the urine:

CASE I.—Reported by Mayo Robson. Woman, sixty-one years old, gave a history of biliary colic for three to four years. No jaundice had been noted in the first year of her illness. In the last two and one half years the attacks of pain were always accompanied by icterus, by rigor, and by deepening of the jaundice. During the short time that the patient was under his observation, Robson noted that she lost considerably in weight, and her symptoms became aggravated. Therefore the question of cancer arose. But the pancreatic reaction in the urine pointed to inflammation and not to carcinoma. At the operation Robson found the pancreatic portion of the common duct packed with large gallstones, and the head of the pancreas markedly swollen. On passing the scoop through the opening in the common duct down to the pancreatic portion, a stone the size of a cherry was extracted covered with offensive pus. This stone, according to Robson, was lodged in a cavity of the head of

the pancreas. A diffuse discharge of bile and offensive pancreatic fluid with pus continued for a week, after which the discharge became gradually less. The patient made a good recovery, and a year later was still well.

**CASE II.**—Reported by Mayo Robson. No less than six eminent physicians had advised operation in a woman of forty-eight, who had jaundice for five months, although her condition was much better than could be expected if the cause was a malignant growth. As the pancreatic reaction pointed to cancer, Robson did not have the slightest hesitation in advising nonoperative treatment.

**CASE III.**—Reported by Moynahan. Patient fifty-seven years old, female. In operating Moynahan found a calculus in the duodenum about the size of a French bean. This turned out to be of pancreatic origin. His diagnosis of pancreatitis had been confirmed previous to the operation, as the pancreatic reaction in the urine was positive for this condition.

**CASE IV.**—Reported by Agabekoff. Patient, sixteen years old, male, entered the hospital complaining of pain in the abdomen. Loss of flesh had been well marked. A physical examination revealed diffuse nodules in the abdominal cavity, slight ascites, and enlarged glands in the neck. He presented the clinical picture of tuberculous peritonitis, the more so as the age was in favor of this condition. Diarrhea had been present and vomiting absent. Pancreatic reaction was positive for cancer. The autopsy showed that almost the whole gland had been affected by cancer originating from the greater curvature of the stomach.

We add to this series our case, in which we were able to arrive at a positive diagnosis of the head of the pancreas by the aid of Cammidge's reaction:

**CASE V.**—R. L., female, sixty years old. Was seen by us with Dr. Sturmdorf on October 12, 1907. Patient belonged to a neuropathic family. She had always been melancholic. Had never had any attacks of gallstone colic, nor had she ever been troubled by indigestion. Six months before our examination she began to complain of a loathing for meat, and four months later jaundice had come on at once. In addition to jaundice, indefinite pains in the abdomen were complained of. The stool was said to be clay colored, and the urine dark in color.

Physical examination showed the visible mucous membranes and the whole skin icteric. The icterus could not have been considered as a deep one. Liver was palpable, gall-bladder not palpable. Spleen not enlarged. By deep pressure high up in the right hypochondrium, patient felt tenderness more pronounced than in the right parasternal line, two fingers above the navel, where some tenderness could also be detected. A tumor mass could not be felt by either of us.

As there was no history of gallstone colic, and the physical examination did not reveal an enlarged gallbladder (as is usually found in malignant disease of the biliary tract or carcinoma of the head of the pancreas), and also as cachexia at that time had not been noticed at all, the possibility of a diagnosis of a chronic pancreatitis arose in our minds. The examination of the feces, which were bile free and offensive in odor, showed a strong acid reaction. Under the microscope fatty needles and fat droplets were observed, but no crystals of neutral fat. Urine of dark brown color showed traces of albumin, hyaline, and granular casts, but no sugar; indican was not in excess.

The urine was tested from albumin by acetic acid and subsequent heating. The "A" reaction showed, in about five hours, a bulky yellow deposit. Reaction "B" gave the same deposit. From both reactions, broad crystals in the shape of rectangles were seen under the microscope. Treated with a 10 per cent solution of sulphuric acid, they disappeared in about six minutes. The examination with methylene was repeated on two subsequent days with the same results.

The diagnosis of carcinoma of the head of the pancreas was made, though we had no other positive symptoms pointing to this condition. The idea of operation was then given up.

The patient died in about six weeks after our examination. The autopsy was performed by Dr. Satterlee whose findings follow:

Body was that of a woman of medium height, considerably emaciated, especially about the face, thin and anorectic. The skin was of a yellow green color, and the mucous membranes were only moderately vascularized. The post-

mortem examination was confined to the abdominal contents. The abdomen was moderately distended, but the abdominal walls showed a panniculus, thicker than normal but pale. The striae on the skin made it apparent that a considerable amount of flesh had been lost.

On opening the abdomen, an enormously distended stomach filled the entire anterior portion of the peritoneal cavity, extending from the ensiform almost to the pubes. On opening the stomach it was found to contain a very large amount (about one and one half quarts) of dark, ochre colored fluid of the consistency of ordinary mockturtle soup. The walls of the stomach were thin, the pylorus practically obliterated because the distention extended through the duodenum to the tumor in the head of the pancreas. The rugae were obliterated, the mucosa congested.

The colon was very small, narrow, and empty. The small intestine was almost empty and contained but little gas.

The head of the pancreas contained an extremely hard nodular growth about one and one half inches in diameter, extending for about the same distance into the pancreas and into the duodenum, which it constricted, surrounding the splenic artery. On section of the growth, it was found to be ulcerated on the surface in the duodenum; deeper in, it was white, extremely firm, and fibrotic. The portion to the left was hemorrhagic. A very small calculus in one of the larger pancreatic ducts was found. The remainder of the pancreas was extremely thin and atrophic. The splenic artery had a slight degree of atheroma.

The common bile duct was patent. No enlarged lymph nodes in this vicinity could be seen or felt. The bile duct was enormously distended with dark greenish viscid bile, but contained no calculi. Apparently the obstruction to the flow of bile had been purely mechanical.

The liver was small, flabby, and elongated from above down; the left lobe was very long and pushed over to the right of the median line. The liver tissue was normal in consistency but very deeply stained with dark green bile, and the bile capillaries were very well marked out. The gallbladder was remarkably distended and tense, showed no evidences of inflammation, and contained about 150 c.c. of dark green bile, but no calculi. The spleen was normal.

The kidneys showed chronic parenchymatous nephritis, were bile stained, contained a few areas of fibrosis; capsules were nonadherent.

The bladder and internal genitalia were apparently normal.

**Anatomical Diagnosis.**—Tumor head of pancreas; intestinal obstruction with dilatation of the stomach; obstructive jaundice, chronic nephritis.

**Cause of Death.**—Intestinal obstruction with dilatation of stomach due to malignant disease of the pancreas (carcinoma), which caused also obstructive jaundice; chronic nephritis.

**Histological examination of tissues from autopsy.**—Tumor of pancreas (a) from the head. Carcinoma with marked myxomatous degeneration, fibrosis and infiltration with polynuclear leucocytes; (b) from the tail. Marked fibrosis and atrophy of glandular tissue. Kidney tissue. Marked chronic parenchymatous degeneration of epithelial cells of convoluted tubules, the tubules distended and contained hyalin casts. Obliterating endarteritis, no increase of connective tissue. Liver tissue. Chronic parenchymatous hepatitis, fatty degeneration and interstitial hepatitis with marked bile pigmentation of liver cells. Obliterating endarteritis.

In conclusion it may be said that the Cammidge reaction has been obtained by us in a few more instances which are also likely to be affections of the pancreas. As in all these cases no confirmatory proof could be given either by an autopsy or an operation, we shall withhold all the material, therefore, for a future paper, when more cases of positive reaction in suspected pancreatic disease may be at our disposal.

## A CASE OF POISONING WITH TANSY (TAN- ACETUM).

By E. J. STOUT, M. D.,  
Philadelphia.

The author deemed the following case worthy of record, as it adds another forcible illustration to the long list of the pernicious habit of counter prescribing, improper, unskilled dispensing, and consequently dangerous use of drugs, and affords an example of the toxic properties of tansy.

Talleyrand, I believe, is credited with the saying: "Language was invented to conceal thoughts," and it would appear that laws regulating the sale of drugs have been made to be circumvented. It is not the writer's intention to accuse the druggists indiscriminately—for happily we have thoroughly reliable and honest men in that profession—but to call attention to the evil referred to above, which has become so common and has been discussed by the medical journals and even by the magazines ad nauseam. It is difficult to understand how any conscientious pharmacist can place a dangerous remedy in an individual's hand without a proper prescription and assume the responsibility and run the risk of a possible death, as a result of his cupidity. Virgil's lines, *Quid non mortalia pectora cogis auri sacra fames*, are as applicable at the present day as thousands of years ago. We have daily examples of this tendency in the human breast when reading the high sounding and misleading advertisements of nostrums in medical journals, unfortunately allowed to appear in the advertising columns, a subject that has been frequently alluded to in print and in the meetings of medical societies. Well might we ask in righteous indignation, *Quo usque abutere patientia nostra?* Mere moralizing, however, will not change the present condition of things one iota; drastic measures are required. If Hercules had stopped to moralize when he undertook to clean the Augean stables, his task would have remained unaccomplished. Could we apply Zeus's heroic treatment, meted out to his son Vulcan (*Iliad A*, line 590):

ὅση γὰρ με καὶ ἄλλοι ἀλεξέμεναι μεμαῶτα  
μυθε, ποδὸς ἑσταγών, ἀπὸ βηλοῦ δισπείβοιο.  
πᾶν δὴ μαρφερόμεν, ἅμα δὴ ἑλίῳ χαταδύντι  
κάπτεσον ἐν Λήμνῳ, ὀλίγος δέ τι θυμὸς ἐν ἧεν,

to this genus homo, what a great benefit it would be to the human race!

Trusting this somewhat flowery preamble may not prove too tedious, the author would refer to the drug as it appears in the *materia medica*. "Tanacetum, or tansy, is described as the leaves and tops of *tanacetum vulgare*, a perennial, herbaceous plant of the natural order compositæ. The flowers and seeds are also endowed with medicinal properties. Tansy is indigenous to Europe, but is cultivated in our gardens, and grows wild in the neighborhood of old settlements. It bears yellow flowers, arranged in a dense terminal corymb. It exhales a strong, penetrating, but not unpleasant, odor when fresh, and its taste is bitter and aromatic. These qualities depend mainly on an essential oil which is most abundant in the flowers and seeds, etc. (Stillé.)" The same author describes the action of the drug as follows: "Tansy, in moderate doses, acts as a gentle stimulant to the digestive organs, and when more freely given produces some general excitement, augments the urine and perspiration, and may bring on nausea, vomiting, and diarrhoea. In overdoses the oil acts as a fatal poison, producing unconsciousness, flushed cheeks, dilated pupils, hurried, stertorous respiration, strong spasms, a full and frequent pulse, repeated convulsions, and then a failing pulse and death." Given in decoction in overdose it does not appear to give rise to convulsions, as noted by Pendleton (quoted below) in a fatal case, differing in this respect from cases of poisoning with the volatile oil. The drug was formerly employed as an emmenagogue, and has diuretic and anthelmintic properties. There are no official preparations, but a fluidextract may be prepared according to the general rule and administered in doses of ℥x to ʒi. The dose of the volatile oil (oleum tanacetii) is 1 to 3 drops. An infusion (tansy tea) may be made in the proportion of ʒi to the pint and used in doses of ʒi-ii.

On January 17, 1907, the writer was hurriedly called to attend the following case at 9 p. m. The patient, a young married woman, twenty years of age, presented the following symptoms: Pulse 160, rapid respiration (40), dilated pupils, clammy skin, more or less rigidity of the muscles of the jaw and legs; she was in a semistupor and unable to answer questions intelligently. Upon questioning the husband, he informed me that his wife, acting upon the advice of a married sister, had taken ʒii of oleum tanacetii for the purpose of bringing on menstruation, at half-past 8 o'clock in the evening. About thirty minutes later, while in the act of disrobing, he heard her fall on the floor. A hypodermic injection of apomorphine hydrochloride (gr. 1/10) was promptly given, and in the vomit the characteristic odor of the drug could readily be detected. This was followed by a liberal dose of spir. ammonii aromatici; in an hour's time the symptoms had improved, respiration becoming less frequent, the pulse more regular, and the patient could respond satisfactorily to questions. Three days later the woman called at my office and stated that the muscles of the jaw still felt stiff and sore, and complained of similar sensations in the muscles of the legs. Judging from the alarming symptoms, it is very probable that the patient would have died, had an emetic not been administered promptly. There was good reason to believe that the drug was not taken with criminal intent, and the woman was entitled to the benefit of the doubt. Careful

questioning elicited a history of irregular menstruation. She began to menstruate at fourteen years of age, but quite irregularly, and there had been amenorrhoea for several months when sixteen years of age; during the last eight months the menses had been entirely suppressed. She had been married for six months; there were, however, no symptoms indicating pregnancy. Four days later the woman informed me that she had commenced to menstruate, probably due to administration of tinct. ferri chloridi. The writer managed to obtain the bottle from which the medicine had been taken and which still contained about  $\frac{3}{4}$  of the oil of tansy; the absence of a proper label and directions and of the pharmacist's name on the bottle aroused suspicion. The patient admitted that she had been instructed by the druggist furnishing the medicine not to mention his name, and she could not or would not remember the place where she had bought the drug.

Tansy appears to be a favorite remedy with the laity in suppressed menstruation, and is regarded popularly as an abortifacient, although it does not possess this power, as has been demonstrated in cases of poisoning with the drug, in which doses of various size, although followed by convulsions and in some instances by death, did not cause abortion. In looking over the literature on the subject, the writer has found several instances of poisoning, following the administration of tansy, which are briefly given.

Dalton (John C., Jr., the *American Journal of the Medical Sciences*, January, 1852, p. 136) describes a case of poisoning with oil of tansy, in which death resulted at the end of three hours and a half, and the quantity of the drug taken was about  $\frac{3}{4}$  and  $\frac{3}{4}$  in a young girl, about twenty-one years of age. The case presented the following appearances: Total unconsciousness, cheeks flushed, of a bright red color; eyes open and very brilliant; pupils of equal size, widely dilated and immovable; sclerotics injected; skin warm, not remarkable as to moisture. Respirations hurried, labored, stertorous, and obstructed by an abundance of frothy mucus. The breath had a strong odor of tansy; pulse quite full, forcible, 128; at intervals of five to ten minutes the body was convulsed by strong spasms, in which the head was thrown back, the respiration suspended, the arms raised and kept rigidly extended, the fingers contracted. This gentleman quotes a case, coming under the notice of Dr. Dalton, of Lowell, of a girl, who took a quantity of oil of tansy just before dinner. After dinner she vomited and immediately fell down insensible and convulsed. She recovered after remaining a long time unconscious. Dr. Dalton (Jr.) speaks of another fatal case of poisoning with oil of tansy, occurring in Boston, under the care of Dr. C. T. Hildreth, which was published in the *American Journal of the Medical Sciences* for May, 1835. In this instance a woman took  $\frac{5}{8}$  of the drug and did not lose consciousness entirely till three quarters of an hour afterwards, though she was convulsed at intervals before that time. After unconsciousness became complete, she did not again recover it, and died rather less than two hours after taking the poison. He concludes by calling attention to the fact that although all the muscles, both of the body and limbs, were for three and one quarter hours subjected to a succession of the most violent contractions, there was no sign of abortion, and after death the ovum was found in the uterus entirely undisturbed.

In Dr. Hildreth's case also, pregnancy existed but

a few weeks advanced, and the drug was undoubtedly taken for the purpose of producing abortion, but nothing of the kind took place. The general symptoms in that case were similar to those described in the foregoing, the most remarkable difference being the more gradual loss of consciousness, and the more rapid death after a much smaller dose. Dr. Chapin (*Boston Medical and Surgical Journal*, 1858, p. 383) describes another occurrence of poisoning in a married woman, who was found in bed, partly conscious, and in paroxysms. The quantity of oil of tansy taken was  $\frac{3}{2}$ ; the woman was four months pregnant, and took the oil to bring about abortion. In an hour the mind became clear and the woman recovered.

John E. Pendleton (*American Medical Times*, ii, 177, March 16, 1861) reports fatal poisoning by decoction of tansy in a negro girl, twenty-one years of age, who had taken a large quantity of strong decoction, for the purpose of producing abortion. She died twenty-six hours after taking the drug. There occurred delirium, slow and laborious respiration, contracted pupils; paralysis of the muscles of deglutition and of all the voluntary muscles ensued. There were no spasmodic or convulsive movements of the body through the whole progress of the case, as has been observed in cases of poisoning by the volatile oil of the drug; abortion did not occur.

It will be seen from the foregoing that a drug with whose properties the laity are but improperly acquainted and whose use may be followed by the gravest consequences should under no circumstances be allowed to be sold promiscuously and without a prescription.

O judgment, thou art fled to brutish beasts,

And men have lost their reason!

Unless energetic measures are taken to suppress the evil, similar cases will continue to occur.

1538 NORTH FIFTEENTH STREET.

#### THE COMPARATIVE THERAPEUTICAL VALUE OF THE COMPOUNDS OF IRON.\*

By R. E. VAN GIESON, M. D.,  
Brooklyn, N. Y.

As introductory to this topic I wish to invite your attention to a brief survey of the present state of our knowledge of hæmoglobin and the metabolism of iron. Somewhat over a half century ago Dr. George B. Wood, in writing of the existence of iron in the blood, stated: "The probability is, that it is united with some peculiar organic principle, having for it an affinity beyond any other body in nature, and capable of being overcome through chemical agency only by the destruction of that principle." It is very remarkable to note that this "probability" of that able clinician expresses very concisely and truly nearly all that we know in regard to this important element at the present day. Long considered as a combination of hæmatin and globulin, it is now known to be a definite nitrogenous element of the blood not separable without destroying its molecular constitution. Hæmatin is a product of destructive analysis. Hæmoglobin is a protein unit. It is the

\*Read before the Medical Association of the County City of New York at a special meeting held at the Hotel de Ville, March 5, 1908.

basic, essential element of the red blood corpuscle and carries literally the breath of life. Its necessary molecule is iron.

The total albumin of the blood is about four per cent. The quantity of iron is less than 0.1 per cent, a surprisingly small amount when we consider the enormous energy developed in carrying oxygen to the remotest tissues of the body, the average adult consuming about eighteen cubic feet of that gas in twenty-four hours. The microscope reveals comparatively few facts as to the structure of the red corpuscle, and physiological chemistry does not add materially to our knowledge, since the chemist can only describe the constituents of dead cells.

We may infer from our present knowledge that the blood corpuscle, inasmuch as it contains normally from eighty-four to ninety-six per cent. of hæmoglobin, is mainly made up of that substance, and that the remainder is an apparently structureless stroma with which the hæmoglobin is united.

Coming now to the metabolism of iron, either as a food or drug, we approach a field which, in spite of the enormous amount of careful research that has been made, is confessedly a *terra incognita*.

Living matter is essentially unstable. Constructive metabolism leads us into a maze of myriads of cells incessantly changing, wherein no fabled thread of Ariadne is found to lead us securely on. A single sentence from Chittenden's *Nutrition of Man* expresses the magnitude and despair of the problem: "Regarding the process of anabolism, as in the construction of living protoplasm out of inert food materials, we can say nothing. This is altogether beyond our ken at present, and doubtless will remain so, since it involves a chemical alteration or change akin to that of bringing the dead to life." Nevertheless, work in this direction has not been entirely futile. We have learned that nearly every foodstuff that enters the human laboratory, with the exception of water, suffers change, and that this is specially true of iron, considered either as a food or medicinal remedy. Melzer, speaking of the metabolism of iron and the changes of ingested iron into hæmoglobin, states: "The normal animal body commands a large reserve fund of iron, which is far in excess over its immediate requirements. The liver, bone marrow, and especially the spleen, are the main depositories for the reserve iron, which is reserved in the form of resistant organic compounds. (This confirms the observation of Carpenter, made some sixty years ago, that the spleen, besides regulating blood pressure, was also an organ of sanguification.) "All ingested and absorbed iron, no matter of what character and origin, goes first to one of these depots, where it becomes converted into organic compounds.

The first function of absorbed iron is to increase the iron reserve.

The ingested iron, no matter of what character, is never utilized directly for the construction of hæmoglobin."

Bearing in mind these important statements so closely connected with our subject, we are better prepared to estimate the comparative value of iron compounds. For practical purposes we can divide them into the ferric and ferrous official preparations, the non-official preparations, of the dispensaries and national formularies; the so-called organic com-

pounds—albuminates, peptonates, caseinates—of which the formulas and methods of preparation are given; and a final class which may be called commercial, in some of which an atomic formula is given, but the method of preparation is known only to the manufacturers. Their names are supposed to indicate their composition. In estimating their comparative remedial value I shall only refer to their use in the tractable forms of anæmia and neurasthenia, where deficiency of hæmoglobin forms the prominent indication for their use.

Direct, primary anæmia from loss of blood is not benefited by iron unless convalescence is retarded. In such cases it is not the lack of red blood corpuscles that makes the real element of danger, but the fall of blood pressure to a point where circulation fails. If the circulation can be maintained there still remains a sufficient number of red blood corpuscles to carry on respiration, and the immediate treatment is to raise the blood pressure within the vessels. Even here, transfused blood from a healthy donor possesses no direct nutritive value, and it is doubtful, at least not proved, that the transfused blood performs the same functions as the original blood of the recipient. A 0.75 per cent. solution of salt, sterilized, injected into the veins, gives all the advantages that can be obtained from the transfusion of blood. If the patient recovers the question of iron comes later on.

At the threshold of our inquiry, the question meets us, Which are to be preferred, the ferric or ferrous compounds?

Ferric salts are supposed to produce insoluble albuminates with the stomach juices, while the ferrous salts give soluble albuminates. But it is contended that the soluble ferrous albuminates are converted into ferric albuminates before absorption takes place. There is, then, practically no real difference, and our choice may be guided more by the palatableness and acceptability to the stomach than by these theoretical suppositions.

It would be foreign to the purpose to attempt to describe each official preparation, the object of this paper being only to consider those that have been and are now in common use. Among the oldest and most useful is the ferrous carbonate in its various forms, which, unless freshly prepared and immediately taken, always contains a variable proportion of sesquioxide.

Dr. George B. Wood, in his *Treatise on Therapeutics*, commends this "both for its gentleness and efficiency. I am in the habit of using it, and calculate with the utmost certainty upon the desired effects from it. In the Pennsylvania Hospital there is a constant succession of patients, especially in the autumn, in the most pitiable state of anæmic debility, often complicated with edema of the limbs, to whom a dose of this medicine three times a day, with a little quinine and nutritious diet, in the course of from two to four weeks, and sometimes even a shorter period, restores healthy color and strength." Its only liquid preparation is the *mistura ferri* composita, a modification of the antihæctic myrrh mixture of Dr. Griffith.

Personally I think I have obtained better effects from iron carbonate by giving it immediately after mixing, and having the ferrous sulphate and potas-

sium carbonate in separate bottles. So prepared and taken the precipitated carbonate is not long enough exposed to the air to produce the sesquioxide. The water used in making the two mixtures should be boiled so as to expel the air. In this way we get nearly the full equivalent of unaltered ferrous carbonate.

Vallet's mass, prepared according to the German pharmacopœia, contains about fifty per cent. of ferrous carbonate. Prepared according to the French pharmacopœia, it contains some forty-one per cent.

Ferrum oxydatum saccharatum solubile contains three per cent. of metallic iron. According to Hager it is not a mere mixture, but a definite compound, in which sugar plays the part of an acid and the iron that of a base. Its solution gives no reaction with potassium ferrocyanide or sulphocyanide; with tannic acid, a very slight opalescence, but no violet or blue black color. To borrow Dr. Wilcox's most appropriate word, the iron seems quite thoroughly "masked," although it is not "organic." Hager states that its introduction into the German pharmacopœia is of the greatest importance. It is mild, but highly efficient. It never irritates even in larger doses, and does not discolor the teeth. It can be added to food without in the least altering the normal taste of the latter. I can only say from personal experience that I can fully testify to the truth of all that Hager has said in its favor, and it should be incorporated in our pharmacopœia. It is especially useful in prescribing for children, as they rarely know that they are "taking medicine." In these cases it is best given in a little weak chocolate or cocoa.

Ferrous sulphate, usually dispensed in pill form, is recommended by Warfinge, of Stockholm, and no doubt is a favorite form of iron with many. I have never used it, on account of its highly astringent and slightly corrosive action on the mucous membrane. Its solution is excessively disagreeable and cannot be disguised by any form of adjuvant.

Ferric phosphates.—Of these the best are the soluble ferric pyrophosphate, official in the pharmacopœia of the United States, and the ferrum pyrophosphoricum cum ammonio citrico (Hager *Pharmaceutische Praxis*, i, p. 1081). The author states: "This preparation, which has the misfortune to possess no empirical or shorter name, is unconditionally a splendid iron remedy, and deserves a more extensive consideration." It differs advantageously from most of the scale salts of iron in being nonhygroscopic, keeps well, is nearly tasteless and easily soluble. It contains on an average 16.6 per cent. of iron.

The ferric salts with the vegetable acids.—Acetates, citrates, tartrates, mallates, and their double salts, in my own experience rank very high. Iron tartrate and potassium, long ago recommended by Ricord in his lectures, is one of our best remedies in postsyphilitic anæmia. The following mixture I have used for many years with good results:

R	Ferri et ammonii citratis,	5v.
	Aque cinnamomi,	f
	Vini ammoniaci,	AA 5vi.
M. S.		

Two teaspoonfuls of this equals about 5 grains. It is agreeable to the taste, acceptable to the digestive organs, and rarely fails to produce the hoped for results.

Iron acetate in the form of Basham's time honored mixture is too well known to need more than a passing allusion. It is official as the liquor ferri et ammonii acetatis.

Dialyzed iron.—Liquor ferri oxychlorati is official in the German pharmacopœia. It has been discarded from the British pharmacopœia. It may be prepared by dialysis or by mixture. Hager states that, prepared by either method, the resulting preparations are chemically identical. It has been objected to because, in contact with the stomach juices, it becomes insoluble, but this is only a transitory condition. It soon becomes soluble and enters rapidly into the intestinal fluids. It is palatable and can be diluted to any extent with distilled water. According to German authorities it should be ranked with the best of iron preparations. The idea of many physicians that the stomach is a dialytic apparatus and therefore must be indifferent is without foundation. Chittenden truly says that dead parchment and the living membrane of the intestines are not to be compared with each other. The living cells that stand as guardians of the portals modify the rate of passage and control absorption.

Reserving one of the best for the last, we take up ferric chloride, the oldest of them all. The official tincture is about the most disagreeable compound of this most valuable salt of iron that could well be devised. A better form is the simple dilution of the official liquor ferri perchloridi to the strength of the tincture and the addition of glycerin. A good formula which I have used for a long time is:

B	Liq. ferri perchlor,	35 parts;
	Aque distillatæ,	65 parts;
		q. s. ad 5x.
	Glycerini,	5ii
M.		

The strength is slightly less than that of the tincture. It is to be noted that iron perchloride solutions, when added to proteid substances, form albuminates, as may be proved by adding it to albumin solutions or with milk. The preceding solution, when given with milk, 10 to 30 drops in 10 to 30 drachms of milk, makes a palatable mixture, does not attack the teeth, and undoubtedly, from the strong affinity of the perchloride for proteids, contains some "masked" or changed iron differing from the perchloride. As a general remedy for anæmia thus administered it will give excellent results, and for the anæmia following or attending rheumatism it is the remedy par excellence.

Organic iron, iron albuminate, caseinated lactate of iron, peptonate of iron, extractum sanguinis bovini.—This group is the result of efforts to attain some form of nitrogenized iron, under the supposition that in such combination they would be more readily absorbed, and consequently more effective as remedies or foods. The formulas for all these can be found in the dispensaries and the National formulary, and can be prepared by any competent pharmacist. Dr. Jackson, of Philadelphia in 1852 prepared a dried blood from bullocks, and for some time it was considered as Nature's remedy for anæmic conditions. The blood is the life. Urgo, fresh or dried blood should make blood. Many of us can recall the dangerous practice of drinking the fresh, warm blood of bullocks at the slaughter house. The results did not justify the very logical

inference. The iron was certainly true organic iron, but it pursued the same path as other forms of iron, and gave no better results, either as a food or tonic.

The last group, comparatively small, are those "organic" preparations that are asserted to be better than those we have long used. In some the atomic formula is given, but their method of preparation is known only to the manufacturers. In the discussion of this class it is hardly possible to be entirely impersonal. I have no ethical prejudice against them, I welcome them with unreserved mental hospitality and cheerful expectancy, I take them experimentally, I prescribe them fairly and with proper judgment as to favorable cases for iron treatment; but thus far I have obtained no better, no quicker results than from the official preparations.

Dr. Laspeyres, of Bonn (*Journal of the American Medical Association*, Literary review, p. 340, 1907), comparing inorganic and organic iron, states: "In the desire to approach the supposed method of Nature there has been a tendency to take up the complex organic preparations to the neglect of those simple preparations which were estimated so highly in the past. The modern preparations cannot be recommended as economical, as the percentage of iron is small and the doses necessarily large." His conclusion is in favor of the official preparations.

Dr. F. W. Warfinge, of Stockholm (*Journal of the American Medical Association*, Literary review, p. 1409, 1907), records results from fifty cases of chlorosis. He states that in chlorosis the effect of iron is not felt unless given in a compound which shows the iron reactions with the ordinary tests.

Dr. Wilcox, in his paper, "Modern Iron Therapy," arrives at a directly opposite conclusion, stating that:

"In determining the form of masked or organic iron for oral administration one should be selected which (1) should be of definite chemical composition; (2) does not precipitate with a silver nitrate solution; (3) does not give the blue black color with MacCallum's test; (4) is not decomposed by the hydrochloric acid of the gastric juice; and (5) it must show definite results in (a) an increase in the number of red bloodcorpuscles, and (b) in the amount of contained hæmoglobin. These requirements are evidently the most rigorous which can be devised, and in meeting them modern iron therapy will be placed upon a secure foundation."

These widely divergent opinions of competent observers must be due to the fact that the older and the more recent preparations in properly selected cases give equally good results, and it is apparent that the rigorous requirements suggested in Dr. Wilcox's paper are not essential to successful treatment.

It is germane to this subject to recall to mind the fact that hæmoglobin percentage when below the normal may be raised without giving iron in any form except as it occurs in the food. Rest in bed, with milk diet and unfermented grape juice, with massage, increases hæmoglobin. The influence of light is favorable in preserving normal hæmoglobin percentage. In animals well fed but deprived of light it falls below the normal. Prison pallor is doubtless due to some extent to reduction of hæmoglobin from deprivation of light. Static electricity is an important aid in improving the condition of impoverished blood. In answer to my in-

quiry on this point, Dr. J. Herman Branth has kindly sent me the following notes:

I have not personally conducted examinations of blood counts, or hæmoglobin percentage, but have read in my medical journals that static electricity elevates the percentage of hæmoglobin. I believe that this is the commonly accepted opinion. I adhere to it, and practice accordingly.

To me personally the principle involved in the cure of anæmia and neurasthenia by the proper form of electricity seems plausible and the results attained confirm the theory. It is generally accepted that protoplasm is stimulated (when below the normal) to greater activity by static electricity, this means improvement in metabolism or the intake of nourishment, and the casting off of waste products. In neuralgia and neurasthenia this process is below the normal, the tissues are underfed, and the accumulated waste acts as toxins to the cells. We know the nerves have no blood vessels, but get their nourishment from the blood vessels in the nerve sheath, and when the blood is impoverished there rises a cry for nerve cell food. This cry we may call neuralgia or a local neurasthenia. In general neurasthenia the whole organism is implicated in this defective metabolism. The concomitants of this condition are general restlessness, undue excitability, loss of sleep, constipation, anæmia, vulnerability to atmospheric changes and to microbic infection, or in general to a reduced resistance to the invasions of disease.

In such a condition, what will the administration of iron do? Will it be absorbed if the organism is suffering from lowered and defective metabolism, and as iron is contained in nearly all our foodstuffs, why does not the organism abstract and assimilate it? We know that under just the conditions described iron in any form frequently passes out of the system without producing any appreciable effect. Now, let us see what happens when we give a case of this kind the static electric bath. In a few minutes it produces unconscious perspiration, sometimes profuse perspiration. In some cases the secretion has such an offensive odor that the room requires ventilation. This certainly indicates the elimination of waste material. *Pari passu* we notice increased heart action. Applying now sparks and spray to the abdomen, we find the peristaltic action of the intestines decidedly increased and evacuations soon follow. Now, if in these forms of defective metabolism we have in electricity a means of eliminating waste products and increasing the heart's action, it is certainly reasonable to expect improved nutrition, and as a result the assimilation of iron given as a remedy is more likely to ensue. I believe most emphatically that electricity in these cases is a most valuable synergist to the favorable action of iron preparations.

Defective metabolism, with its attendant evils of autointoxication and constipation, are very serious impediments to the favorable action of iron compounds. If we give iron in such cases perfunctorily and indiscriminately, we fail to attain the full benefit of the remedy. There may be a temporary improvement, but the conditions which are causative of the anæmia are not controlled, and unfortunately in many cases cannot be, as the circumstances of the patients will not permit them to lose the time and incur the expense of proper preparatory treatment.

To sum up:

A careful study of iron metabolism shows that the official preparations of iron so long useful in the past will increase hæmoglobin.

The ferrous carbonate; the soluble oxide with sugar; the double salts with the vegetable acids; the solution of the perchloride given in combination and largely diluted with milk, are the forms most likely to produce good results.

Directly conflicting views as to the value of the modern proprietary preparations exist among competent observers.

In all iron medication the question of defective metabolism is important.

Cases must be individualized and preparatory treatment is essential.

Rest in bed, massage, milk diet, unfermented grape juice, and static electricity are valuable adjuvants preparatory to or during the administration of the iron compounds.

94 KENT STREET.

# THE SURGICAL TREATMENT OF APPENDICITIS.\*

By JOHN EGERTON CANNADAY, M. D.,  
Wheeling, W. Va.,

Surgeon to the Reynolds Memorial Hospital.

The surgical treatment of appendicitis resolves itself into the treatment of chronic cases, acute cases, and pus cases.

In the first and second class of cases I believe in the unqualified removal of the appendix, first, last, and always. In the third class of cases I simply incise and drain, removing the appendix, provided the condition of the patient warrants the interference and provided that the appendix can be secured without breaking down the wall of adhesions that has been formed between the abscess cavity and the general peritoneal cavity.

To successfully cope with the many and sundry shadings, intricacies, complications, and combinations of these three more or less arbitrary classes will at times tax the skill and ingenuity of the most accomplished operator. The chronic cases, unless there are numerous adhesions, can be dealt with through a small incision. When the adhesions are numerous and many difficulties stand in the way of locating, much less removing the appendix, a larger incision with its added room will be required. Again, the skilled surgeon can accomplish through a short incision that which the tyro could only accomplish through a long incision. The incision preferred is a short gridiron; this when closed by tier catgut and healed primarily should never result in hernia. When used for drainage and a small drain used hernia will seldom follow.

When more room is needed, as, for instance, in the dissection of dense adhesions, an incision of fair length in the rectus is more desirable. The muscle fibres should be separated without the division of nerve trunks so as to avoid subsequent muscular atrophy in the abdominal wall.

Pick up the appendix, apply a hæmostat about its middle, ligate its mesoappendix with catgut, including the entire meson in the grasp of the one ligature; an artery forceps is placed on the mesoappendix between the appendix and the ligature for the protection of the latter when the appendix is being freed. A forceps is clamped on to the appendix flush with the cæcum, a second hæmostat is placed just above the first and gradually worked upward for about one quarter of an inch, forcing the contents of the appendix before it. The appendix is now amputated with knife or scissors, flush with the jaws of the forceps applied next the cæcum, and the cut surface touched with the thermocautery or a little carbolic acid on a cotton tipped applicator, followed by alcohol. I invert the appendix by the purse string method with ten day chronic catgut

of medium size threaded on a round pointed needle. Beginning at the point of attachment of the meso-appendix, the needle is carried under the artery supplying the appendix and again under this vessel for the second time, obliterating the vessel as if it had been tied; two or three turns of the needle are taken into the cæcum on either side of the base of appendix. When the handle of the artery forceps is reached the ligature is carried over instead of under in such a manner that when the ligature is drawn taut and the handle of the forceps raised a ring of the cæcum is readily drawn up over the amputated stump of the appendix with much ease. This method is described by me in detail with cuts in the *Journal of American Medical Association* of June 1, 1907, XLVIII, page 1865.

The inversion site is reinforced by a few Lembert sutures of ten day catgut.

Drainage is not used unless it is deemed absolutely necessary. In my own practice I have reversed the old dictum, "When in doubt, drain," and when in doubt I do not drain. In a number of drainage cases it is an advantage to carry the drain through a small stab wound, so that the operation wound may be closed in the usual manner by layer sutures.

At times pus cases are so situated that postperitoneal drainage can be used, but this does not happen very often. Some of the postcæcal abscesses can be appropriately drained through the loin; when an abscess cavity has to be drained remove the appendix, provided it can be gotten out without breaking down the abscess wall; otherwise leave it until after the abscess and its resultant sinus have closed, then do a secondary operation for its removal.

I believe that all patients with appendicitis should be operated upon irrespective of the stage of the trouble. When the case is one of general peritonitis or extensive local peritonitis a small incision should be made and a cigaret drain inserted, no more, no less. Irrigation, sponging, and mopping out, breaking up adhesions, etc., in such a case, would be murderous. Postural drainage is undoubtedly of some value in these cases. I greatly favor having the patient lie on the side in which the drain has been placed for a few hours at least immediately after the insertion of the drain. The administration of normal saline enemata to the patient who is weak or exhausted gives valuable support.

KEESLER BUILDING.

## REPORT OF A CASE OF CEREBRAL ABSCESS WITH MASKED SYMPTOMS.\*

By ROBERT EMMET COUGHLIN, M. D.,  
Brooklyn, N. Y.,

Assistant Surgeon to the New York Hospital.

The following case was admitted on October 14, 1907, to the New York Hospital, medical division, under the service of Dr. Edward P. Cornwall:

Mrs. J. A. C. (with previous hysterectomy), 40 years of age, single, New York.

Family history: Mother, sister, and two brothers died of pulmonary tuberculosis; one brother died of tubercular meningitis.

Past history: No disease of childhood that she remem-

\*Read by author before the Kentucky State Medical Association, Louisville, Ky., October 1907.

\*Read before the New York State Medical Society, December 1907.

bered. Except for two attacks of rheumatism she had always been perfectly healthy. Two years ago she had a severe earache in her right ear, which was relieved by a sinupism applied to the back of her neck; discharge was not present. Menstrual life began at fifteen; twenty-eight day type, lasting from two to three days; rather painful; moderate in amount. Patient had one child, seven months old, no miscarriages. She took an occasional glass of beer, no tea; coffee, three or four cupsful a day.

Her present trouble began two months ago, commencing in a constant, sharp headache, slightly worse at night; always located in the right occipital and parietal regions. She vomited occasionally; the same had no reference to meals. Once or twice the vomiting was rather forcible. She had attacks of vertigo, also visual hallucinations, but never any paralysis or epileptic attacks. Her control of bladder and rectum was perfect, bowels were constipated.

Examination: Patient looked poorly nourished; complexion was fair; lips and conjunctivæ were anæmic, tongue slightly coated. Teeth were in fair condition. Pulse was regular, small, of low tension, vessel wall was not thickened. Pupils were equal and reacted to light. Heart and lungs were normal. Abdomen and extremities were normal. Urinalysis: On October 17, 1907, showed specific gravity 1.018, urine straw colored, triple phosphates present, very fine trace of albumin present, no sugar. There were present a heavy sediment, mucus and debris, epithelium and white blood cells.

Diagnosis: Held in reserve.

Treatment: Purely symptomatic.

Epitome of family history, past history, and present condition. Family history of tuberculosis very strong. No diseases of childhood. Pain in right ear two years ago. Occipital headache on right side of head constant and worse at night. Forcible vomiting. Vertigo. Poorly nourished patient. Anæmic. Small low tension pulse.

On October 20, 1907, eyes were examined by the consulting ophthalmologist and found to be entirely normal, not even a congestion of the vessels of fundus.

On October 21, 1907, the consulting physician examined his patient and thought the condition due to anæmia, malnutrition, and decayed teeth.

On October 31, 1907, the consulting neurologist examined the patient and did a lumbar puncture, but a dry tap was obtained. On the same day an aurist examined ears and only a congestion of right drum was found.

Blood count: On October 31, 1907, showed white blood cells, 18,000; polymuclear cells, 86 per cent; lymphocytes, 11 per cent; eosinophiles, 1 per cent; mast cells, 2 per cent; hæmoglobin (blotting paper method), 90 per cent.

On November 1, 1907, the attending surgeon decided that patient could not be operated upon until something more definite could be localized.

On admission the temperature was 99.6° F.; the highest temperature being 101° F.; lowest temperature 97.2° F. The average morning temperature was about normal; the average evening temperature was 99.4° F. Five days prior to death a normal temperature was present.

The pulse rate ran from 82 on admission to 145 before death. Lowest pulse rate 68.

The respirations never varied from 20 to 24 throughout.

In spite of all treatment the headache continued until November 2d, when patient became stupid but answered questions rationally. Suddenly at 5 p. m. breathing became very slow and shallow. Pulse kept fairly strong, later becoming thready and slow, until death occurred at 6 p. m.

Necropsy: Upon opening the calvarium an irregular, burrowing abscess in the left hemisphere just external to the lateral ventricle could be made out. This burrowing pus could be traced to a small opening entering the right ear. The base of brain was covered with exudate. A complete post mortem examination was not performed, by request of family.

**Conclusions.**—Briefly stated, here was a case of a young woman with a strong family history of tuberculosis; a history of pain in her right ear without any discharge of pus two years previously; a pain in right occipital and parietal region coming on two months before her admission to the hospital, this pain being constant and unrelieved by treatment and worse at night; forcible vomiting; vertigo; anæmic; a low tension of 18.000; low tension pulse; patient

dying after all apparent means had been employed to locate her disease; and the necropsy showing the diseased condition in the left hemisphere of the brain, where there had never been the slightest sign to indicate the location of the abscess in this situation. Had the consulting surgeon operated over the site of trouble as indicated by the symptoms he never would have reached the diseased area.

Operative evacuation of the abscess is the only treatment that can be considered, yet how impossible it is to operate when the symptoms bear no relation to the location of the abscess, as in this particular case. Without such an operation the disease is, of course, fatal.

The statistics of Korner show that there is hope in many of these cases by operation. Of seventy-six cases in the cerebrum, forty-two patients were cured, thirty-four patients died; of sixteen cases in the cerebellum, nine patients were cured, seven died, i. e., 56 per cent. of each were cured by operation.

Greene, in the *International Textbook of Surgery*, says: "To wait till a complete diagnosis of the presence and situation of an abscess is in the majority of cases to lose the only opportunity of saving life, for the full development of symptoms necessary for such a diagnosis in most cases show themselves only in the latest stages, just before death, when the vital forces are so reduced that operative procedure is not justifiable. For a fair chance of success the operation must be done early; and the fact already stated, that in 92 per cent. of otitic abscesses of the brain the bone is diseased directly to the dura, justifies and demands an exploration of the bone, even on slight suspicion of brain disease. If this is done by exposing the ear cavities by the so called radical operation, the disease can be followed inward from its source to the brain."

428 FORTY-SEVENTH STREET.

## Therapeutical Notes.

**The Local Treatment of Diphtheria.**—J. T. MacLachlan contributes to *The British Medical Journal*, for March 21, 1908, a note on a case of diphtheria in which recovery followed the application of a paint consisting of a solution of equal parts of liquor hydrargyri perchloridi and glycerinum acidi tannici, of the *British Pharmacopæia*. He was called to see a child on January 5, 1908, and found it was suffering from diphtheria, there being considerable patches of membrane on both tonsils. The face was pale and puffy, and the pulse was soft. He ordered the paint to be used every two hours, telling the mother the object was to kill the germs in the throat. The mother, in her anxiety to get the child well, actually painted the throat every hour, and in thirty-six hours all trace of membrane had disappeared and the child seemed well again, except that she was weak and anæmic. The paint was continued for several days, at longer intervals, and then stopped and an iron tonic prescribed. On January 20th a bacteriological examination was made and the bacillus of diphtheria was found. The paint had been stopped too soon. The lesson which MacLachlan derives from this experi-

ence is to paint hourly, day and night, until membrane is gone, then continue the application at suitable intervals for a week or longer, or until the swab test is negative. The following is his form of prescription::

- R Liq. hydrarg. perchlor. .... 3i;  
Glycerini acidi tannici. .... 3i.

M.

The author says he has used this paint for many years, ordering it to be applied every two hours, unless during sleep, and has found it only fail on one occasion to clear up the throat, when he used antitoxic serum.

**Sprays for Laryngeal Tuberculosis.**—The following formulas are credited Lemoine and Mendel, respectively, in *Journal de médecine de Paris*, for March 14, 1908:

# I.

- R Boric acid, ..... 5iiss;  
Sodium borate, ..... 5iiss;  
Cocaine, ..... gr. ii;  
Glycerin, ..... 3i;  
Boiling distilled water, ..... 3vi.

M.

# II.

- R Balsam of Peru, ..... ʒi viii;  
Tincture of eucalyptus, ..... aa 3i;  
Tincture of quillaja, ..... ʒi lxxv;  
Distilled cherry laurel water, ..... 5iiss;  
Distilled water, ..... 3xvi.

M.

**Sodium Nitrite in Therapeutics.**—Sodium nitrite has been used for some time in therapeutics. It is a drug which requires to be used with caution, because it is poisonous in comparatively small doses, and fatal cases of poisoning are recorded. It is a white salt, readily soluble in water, and it is ordinarily prescribed in aqueous solutions, in doses of two to five grains during twenty-four hours. It is of value in cases of chronic arterial hypertension, according to M. Vaquez (*Archives des maladies du cœur, des vaisseaux, et du sang*, January, 1908), who prescribes the following syrup:

- R Sodium nitrite, ..... 5ss;  
Tincture of melissa, ..... ʒi lxxv;  
Distilled water, ..... 5iiss;  
Simple syrup, ..... ad 3vi.

M. Sig.: One teaspoonful three times a day, the patient taking the medicine for five days and suspending treatment another five days, when the medicine is resumed.

M. Raymond (*loc. citat.*) recommends the hypodermatic administration of sodium nitrite in the treatment of the lightninglike pains of locomotor ataxia. He uses a ten per cent. solution, injecting fifteen minims during the day [? in divided doses] for six days, then suspending treatment for ten days, after which it is renewed for a fresh period of ten days, thirty minims being administered daily in divided doses. The treatment is again suspended as before, and renewed after the interval of rest in doses of forty five minims a day.

**American Wormseed Oil for Ascaris.**—The value of the oil of American wormseed (*Chenopodium anthelminticum*) in the treatment of ascaris is attested by Brunning, of Rostock (*Pharmazeutische Zentralhalle*, March 10, 1908, p. 234), who gives it in from eight to fifteen drop doses, according to the age of the child; every hour for three

hours, in sweetened water, followed by a laxative. If it is not retained readily, or gives rise to colicky pains, when given in this way, it should be taken in a draught of warm milk.

[American wormseed oil is distilled in this country, in the neighborhood of Baltimore, from the entire plant, *Chenopodium ambrosioides* L. var. *anthelminticum* Gray.—ABSTRACTOR.]

**A Middle Ear Inspirator.**—In a communication to the *Journal of the American Medical Association* for March 28th, Percy R. Wood describes an instrument he has devised for the inflation of the

Middle ear inspirator. A, medicated cotton; B, vacuum; C, rubber tip for insertion into nares.

middle ear by the patient at his home. He first calls attention to the fact that tinnitus aurium, which is frequently an annoying and persistent sequel to acute and chronic Eustachian and middle ear catarrh, is often permanently relieved by inflation of the middle ear for a prolonged period. A prolonged course of office treatment is, however, denied to many patients on account of lack of time or means, and for the benefit of such he hit upon the construction of the instrument illustrated, which consists of a glass

tube bent on itself. One extremity is shaped for insertion into one nares, while the other retains the medicament and is inserted between the lips. When charged and in place a sudden expiration forces the medicated vapor into the middle ear. The author says that persistent application of this instrument for weeks or months permanently relieves tinnitus and morbid conditions of the Eustachian and intratympanic membranes in a large percentage of cases. The following solution is used to impregnate the cotton and supply the medicated vapor:

- R Chloroform, ..... 3ii;  
Ether, ..... 3i;  
Alcohol, ..... 3i;  
Oil of rose, ..... enough to scent.

M.

**Zittmann's Decoction.**—In *The Journal of Cutaneous Diseases*, for April, 1908, Professor Montgomery, of the University of California, revives an old and greatly neglected remedy, animadverting at the same time on the present day subserviency of clinicians to chemists. Montgomery believes it is just as erroneous to conclude, because a drug has certain chemical properties, that it must necessarily be of value in a given disease, as to assert that, because a medicament does not answer to certain chemical requirements, it is valueless. Zittmann's decoction at one time enjoyed a great and deserved popularity in the treatment of syphilis, but because the chemistry of the day asserted that the mercury used in it was insoluble, and therefore could never reach the patient, it fell into disuse. Now, through chemistry, it is known that mercury

is present in the finished decoction, and in a very digestible form. He admits that chemistry has done infinite good to the practice of medicine and believes that the hope for future advance lies largely along chemical lines; but "what is objected to is subservience to chemistry, and often to men who never saw a patient." The author gives a minute description of the old way of making Zittmann's decoction, and he emphasizes the necessity of seeing that the instructions are implicitly followed by the druggist who is entrusted to compound it, even if it becomes necessary to "sit over him with a cocked pistol in your hand while the necessary steeping and boiling is being carried out." It is especially difficult to get the instructions fulfilled, Montgomery says, "if the apothecary is over clever and enterprising." The formula of the original preparation is cited by him as follows:

B Sarsaparilla root, .....	100.0 grammes;
Water, .....	2600.0 grammes.

Then add well mixed up and in a linen bag:

White sugar, .....	6.0 grammes;
Powdered alum, .....	6.0 grammes;
Calomel, .....	4.0 grammes;
Cinnabar (mercuric sulphide), .....	1.0 gramme.

Allow to stand over night in a covered porcelain or earthenware vessel. The next morning simmer gently for eight hours. Then add:

Fennel seed, .....	4.0 grammes;
Anise seed, .....	4.0 grammes;
Senna leaves, .....	24.0 grammes;
Licorice root, .....	12.0 grammes.

The leaves should be first brayed in a mortar and then cut fine.

Allow the mixture to stand for three hours and then strain off 2,500 grammes.

This should be labeled Zittmann's decoction (strong).

The weak decoction is made as follows: Take the dregs left after straining off the strong decoction, and add to them:

Sarsaparilla root, .....	50.0 grammes;
Water, .....	2600.0 grammes.

Boil gently as before for three hours, stirring frequently, and add:

Lemon peel, .....	
Cassia bark, .....	
Icicore root, .....	
Short cardamom seeds, .....	ãã 3.0 grammes.

Allow to stand for three hours and strain off 2,500 grammes.

Bottle and label Zittmann's decoction (weak).

The dose of the decoction varies. A wineglassful each of the strong and of the weak is a moderate dose. If it proves too laxative, less may be given. Sometimes large doses are ordered, as a pint of the strong in the morning and a pint of the weak at night, but this is unusual. If the patient is kept in bed, and the decoction is taken warm, it is said to add to its efficacy.

Montgomery says that the decoction may be given also as a mild alternative between courses of inunctions or injections of mercury, or after the prolonged administration of potassium iodide.

**Thymol in Whooping Cough.**—Berger (*Therapeutische Rundschau*, March 22, 1908) says he has met with astonishing success in the treatment of whooping cough by the use of a one tenth of one

per cent. solution of thymol given as an inhalation every three hours, in the following prescription:

B Thymol, .....	gr. viiiss;
Absolute alcohol, .....	℥ lxxv;
Distilled water, .....	℥ xvi.

M.

The thymol will not remain in solution unless the bottle is kept in a warm place at a temperature about 68° F., and it may be necessary to place it in warm water before using, in order to redissolve the thymol.

**Mistura Ferri Aperiens.**—The *Philadelphia Hospital Formulary* (edition of 1899) does not list a preparation bearing the name *Mistura ferri acida*, but under the heading *Mistura ferri aperiens* the following is published:

B Iron sulphate, .....	gr. xvi;
Magnesium sulphate, .....	℥i;
Diluted sulphuric acid, .....	℥i;
Syrup of ginger, .....	℥i;
Infusion of quassia, .....	q. s. ad ℥viii.

Dose: Tablespoonful.

It will be perceived that the quantities of magnesium sulphate and diluted sulphuric acid in this formula are identical with those prescribed in the formula for *Mistura ferri acida* printed in the preceding number of the *Journal* on page 648, but the amount of iron sulphate is reduced and the mixture is made up to eight ounces.

**For Gastric Hyperasthenia.**—The following prescription is attributed to Robin (*Gazette médicale de Nantes*, March 14, 1908):

B Tincture of cocculus, .....	℥iiss;
Tincture of hyoscyamus, .....	
Tincture of belladonna, .....	
Tincture of cannabis indica, .....	
Tincture of opium, .....	ãã ℥i.

M. Sig.: Ten drops at noon and night before meals, and five drops before breakfast.

Another prescription, said to be more effective, is the following:

B Atropine sulphate, .....	gr. 1/7;
Picrotoxine, .....	gr. 1/2;
Alcohol sufficient to dissolve; .....	
Distilled water, .....	℥x.

M. Sig.: One tablespoonful twice daily, before meals, at noon and evening.

**Gargle for Chronic Pharyngitis.**—The following is credited to Eudler in *Journal de médecine de Paris*, for March 14, 1908:

B Zinc sulphate, .....	gr. iiii;
Peppermint water, .....	℥i.

Sig.: Use as a gargle three or four times a day.

**Application for Pruritus Ani et Vulvæ.**—A paste of the following composition may be applied to the parts affected:

B Salicylic acid, .....	gr. xxx;
Phenol, .....	gr. xv;
Tartaric acid, .....	gr. xlv;
Glycerite of starch, .....	℥i.

M.

To be followed by the free use of a dusting powder:

B Powdered talc, .....	℥vii.
Zinc oxide, .....	℥i.

M.

**Application for the Prevention of Bedsores.**—The following, applied as a varnish twice daily to the parts menaced, will act as a preventive of bedsores:

Guttapercha, .....	℥i;
Chloroform, .....	℥i;
Balsam of Peru, .....	gtt. xv.

## THE STATE CHARITIES AID ASSOCIATION'S WORK IN THE CAMPAIGN AGAINST TUBERCULOUS DISEASE.

The State Charities Aid Association is playing a very commendable and efficient part in the effort, undertaken jointly by itself and the Department of Health of the State of New York, to curb the inroads of pulmonary consumption on the public health. Not the least praiseworthy of its activities is the maintenance of a "press bureau," by means of which authentic information is furnished weekly to about 500 newspapers, principally in the State of New York.

We are indebted to the association for a recent issue of its publication, dated March 24th, in which attention is called to the advantage likely to accrue to the Chinese by the forthcoming translation into the Chinese language of Dr. S. Adolphus Knopf's famous prize essay, which we have already announced as about to appear. To some extent, it seems, the preparation of the translation is a result of the association's "press bureau." It is stated in the issue before us that, in reply to an inquiry recently sent out for the purpose of ascertaining whether or not it was the opinion of the editors who received the association's publication that such service was worth while, a letter was received from Mr. Charles M. Fahs, a missionary editor, stating that he thought the service extremely valuable and, adding that he often sent the material to medical missionaries, and that one of them, Dr. George A.

Stewart, connected with a number of farm missions in China, having received from Mr. Fahs a copy of Dr. Knopf's essay, had written to Dr. Knopf for permission to have it translated into Chinese. Dr. Stewart wrote also that the people of China suffered severely from consumption and knew nothing about hygienic methods of combating it.

## THE AMERICAN SOCIETY OF TROPICAL MEDICINE.

The fifth annual meeting of the American Society of Tropical Medicine, which was held in Baltimore, at the Johns Hopkins Hospital, on Saturday, March 28th, was a notable one. In the five years of its existence this society has provided a centre for the distribution of information about tropical diseases and has acted as the rallying point for the increasing number of medical men returning from the tropical climates of the world. Not only are the activities of this body of men of interest to physicians and sanitarians returning from the tropics, but they are or should be of interest to all the practitioners of medicine in the lower austral zone of the United States, which comprises the Carolinas, Georgia, Florida, Alabama, Mississippi, Arkansas, Louisiana, Texas, Arizona, New Mexico, and southern California. In all these districts, with the possible exception of southern California, malaria is present in greater or less amount. There is still much to be learned by original investigators about this disease; but there is much more to be learned about it by the general practitioner. In this region also intestinal parasites are more common than in the more temperate climate found above the thirty-sixth parallel of north latitude. The study of the fæces in all cases of chronic gastrointestinal disorder is rapidly producing results which make all the inconvenience of the process well worth while.

While it is quite likely that kala azar and trypanosomiasis will never be found in our own home territory, except as imported diseases, as plague and cholera are occasionally imported, still there is enough work, which is properly classifiable as tropical, to be done to interest an increasing number of medical men.

The programme of the society was carried out in the main as indicated in the news columns in our issue of March 21st. Mr. D. E. Lantz, of the United States Department of Agriculture, gave a very interesting account of the habits of rats, and described the best methods of catching them. Dr. F. E. Russell, of the Army Medical Museum, read a paper on the comparative morphology of *Treponema pallidum* and *Treponema carterii*. Dr. Ferris, of Dr. Roscoe

feller Institute, gave a demonstration of living and stained trypanosomes and spirochætae. The sessions of the meeting, one held in the morning and one in the afternoon, were attended by about a hundred members and guests.

### THE GOLITZYN HOSPITAL.

The Russian physicians' accounts of the casualties of their armies during the Russo-Japanese war are now being brought to the notice of their foreign confrères. We have received a report of the work of the temporary structure of the Golitzyn Hospital in Moscow, edited by Dr. S. Derügingy, chief physician of the hospital.

The charity of the Russian nation during the war was boundless. Rich and poor alike contributed funds for the care of the wounded, for the improvement of the condition of the soldiers at the front and on the march, etc. The Golitzyn Hospital was founded and is supported by the princely family of Golitzyn. The present chief of the family, Prince Sergius Michailovitch Golitzyn, gave the building for a temporary war hospital and provided twenty beds; Mr. Nicolaus Dmitrievitch Selesnev, ten beds; and the Teamsters' Guild of Moscow, twelve beds. Thus the temporary hospital contained forty-two beds and was equipped with a full armamentarium, including a Röntgen ray apparatus provided by Prince B. D. Sidamon-Eristov. Dr. Derügingy supervised the hospital and attended to the surgical cases and operations, Dr. G. J. Pribytkov took charge of the nervous diseases, and Dr. V. N. Spassky treated the other medical cases. Besides these three regular physicians at the Golitzyn Hospital, there were engaged four gentlemen as assistant house physicians at a nominal fee of eighteen dollars a month. Five women volunteered as nurses. Thus it was made possible that the cost of each bed was only one ruble (about sixty-five cents) a day.

From June 18, 1904, to April 10, 1906, 210 wounded and seventy sick soldiers were received, having been sent from the front, which circumstance meant a long and tedious trip. The wounded had certainly received some treatment, not merely "first aid," at and near the battlefield.

Of the 210 wounded, four died, one after an operation for tuberculous coxitis, one from internal hæmorrhage (a hæmophilic), and two from sepsis, having arrived at the hospital very septic. Of the seventy sick, seven died, one of carcinoma of the stomach and six of tuberculous disease of the lungs. Of the sick soldiers, twelve suffered from septic middle ear inflammation, four from emphysema and bronchitis, two from pleurisy without exudation, fifteen from pulmonary tuberculous disease, two

from subacute enteritis, one from perityphlitis, two from typhoid fever, two from syphilis, one from a sequela of gonorrhœa, three from sciatica, three from traumatic nervous disturbance, and two from epilepsy. Eleven were classified as neurasthenics.

Among the wounded, there were seventeen injuries of the cranium, twenty-seven of the brain, and seven of the spinal cord. Three successful trephinations were performed. Ten soldiers were treated for paralyses of peripheral nerves, and in six cases bone sutures were applied for ununited fractures (two in soldiers who afterward died from sepsis). Two operations for aneurysm were performed with good final results. Bullets and metallic splinters were taken out in eighteen cases, while in eight cases the foreign bodies were left in place. The lung was injured in sixteen cases, the abdominal cavity in six, and the spinal column in seven. Simple injuries of the long bones and joints by bullets were treated in thirty-eight wounded, multiple injuries in six. Nine cases presented injuries to other parts of the body, while twenty-eight patients were operated upon for diseases which were not contracted in the field. This short synopsis shows the great variety of cases. Some of the wounded soldiers arrived at the hospital a year and a half after the injury.

### CARRIERS OF THE MALARIAL PARASITES.

Two years ago there were only six mosquitoes which had been definitely settled to be capable of transmitting malarial disease from man to man. These were *Anopheles maculipennis*, *Anopheles bifurcatus*, *Myzomyia funesta*, *Pyretophorus costalis*, *Cellia argyrotarsis*, and *Cellia albipes*. Others were suspected, but there was a doubt. In the second edition of *Tropical Diseases*, by Sir Patrick Manson, 1907, there is a list of twenty-six other members of the family *Anophelina* which have "been shown with more or less precision to be efficient hosts of the malaria parasites." The notable species included in this list are *Myzorrhynchus Lutzii* for Brazil and *Myzomyia Rossii* and *Myzorrhynchus sinensis* for India (the latter also for Japan). In the December number of the *Philippine Journal of Science* there is an interesting article by Mr. Charles S. Banks, entomologist in the Biological Laboratory of the Bureau of Science of Manila, describing the methods by which he succeeded in showing that *Myzomyia Ludlowii* should be added to the list. Mr. Banks's work was done at the navy yard at Olongapo and at the marine rifle range at Maquinaya, where malarial fever of a very pernicious type was prevalent. Among other interesting facts observed in the course of the study, the development

of *Myzomyia Ludlowii* larvæ into pupæ and imagoes in salt water was not the least in importance. The development of the gametocytes into the ookinete and into the sporozoites has been definitely traced in this mosquito, and one person has been experimentally infected by the bite of an infected insect.

### THE COUNTRY DOCTOR.

This is a well worn theme, but it puts on fresh attractiveness under the touch of Dr. N. A. Powell, of Toronto, professor of medical jurisprudence and associate professor of clinical surgery in the Medical Department of the University of Toronto. His address on the subject was published in the March number of the *Canadian Journal of Medicine and Surgery*. It was first delivered in 1890 before the students of Trinity Medical College, and it is so good that we do not wonder that it was repeated by request seventeen years later, in 1907, before the Medical Society of the University of Toronto.

Dr. Powell tells us that for ten years he was himself a country doctor, but that it is not his own story that he recounts. He evidently had other country doctors under observation, and the composite photograph which he carries in his mind, and of which his address is an impression, is a well deserved tribute to the country doctor in general. There may be an occasional black sheep in the ranks, but the average country doctor is such as Dr. Powell depicts him. "The glory of optimism pervades his life." "He is the best friend a community can have. He is the confidant of lovers, and helps to make up their quarrels. He brings together again the husband and wife, whom differences have separated. He is father confessor to half the country, and keeps his trust with knightly honor. His sympathy is deep and genuine, and is not worn upon his coat sleeve. No one more than himself feels contempt for a 'gusher' in or out of his profession."

The address overflows with humor. The author quotes Father Faber as having once said: "There is no greater help to a religious life than a keen sense of the ludicrous." He tells us that "an evangelist at one time got into the habit of calling his audiences 'Dear souls.' Laboring in Ireland, he used to say with effect, 'Dear Belfast souls,' 'Dear Dublin souls,' but when he said 'Dear Cork souls' it did not seem quite so appropriate."

A grand man is the country doctor as portrayed by Dr. Powell, but he is not perfect. "To be perfect," he says, "an ideal doctor, he would need to have the wisdom of Solomon, the patience of Job, the strength of Samson, the bravery of Joshua, the eloquence of Paul, the meekness of Moses, the

faithfulness of Abraham, the charity of Dorcas, and the executive ability of Jezebel. He would have to hunt like Nimrod, fish like Peter, climb like Zacheus, and drive like Jehu. He would have to keep clear of the gout of Asa, the melancholia of Saul, the gastric infelicity of Timothy, and would still fall short of perfection if he had not the tireless perseverance of the devil himself." We have quoted Dr. Powell's own words freely, feeling that any attempt to paraphrase them would detract from their expressiveness. We hope that many of our readers will be fortunate enough to obtain the entire text of the address.

### EXPERIMENTAL VALVULAR LESIONS.

The old method of damaging the valves of the heart, in experimental pathology, by introducing instruments into the heart through the vessels of the neck, was of some value, but it was impossible to regulate the nature and degree of the damage with any degree of certainty. Recently Dr. Cushing and Dr. Branch, of Baltimore (*Journal of Medical Research*, February), taking advantage of McCallum's improved valvulotome, which is inserted directly into the chamber through the heart muscle, have evolved a technique whereby they can induce either regurgitation or stenosis at will. The respiration is controlled by direct inflation through a tracheotomy tube, and the heart is exposed by a muscle splitting operation, the sixth rib being resected. The valvulotome is then inserted into the heart and the valve cusps or chordæ tendineæ divided if it is desired to bring about regurgitation. To induce stenosis a suture is passed around the chordæ tendineæ or through the cusps. Lesions induced in dogs in this manner give rise to signs and symptoms closely resembling those found in human patients with corresponding valvular defects. Of twenty-five dogs subjected to this experiment, eleven recovered, while eight died during the operation and six died later from infection, to which dogs seem peculiarly liable after operations about this part of the body.

The authors not only believe that much may be learned from such studies, but they regard it as possible that the technique may be so improved that it will be feasible to divide a stenotic mitral valve in the human subject, a procedure which, they state, was conceived by Sir Lauder Brunton six years ago (*Lancet*, 1902, i, p. 352). In certain cases it might be justifiable to subject a patient to considerable risk in order to relieve him of the progressive results of a contracting mitral valve. Cushing and Branch do not consider that our present knowledge would justify such an attempt. The new

dog on which they had an opportunity of putting their theory to test certainly upheld them in this position. Not only did the animal die during the operation, but the post mortem disclosed no sign of stenosis, notwithstanding the fact that the diagnosis had been made by eminent clinicians.

#### DR. STANFORD E. CHAILLE'S JUBILEE.

It is singularly appropriate that the alumni of the Medical Department of Tulane University, as well as his many friends, purpose to celebrate the fiftieth year of teaching service of Professor Chaillé, the celebration to take place on May 19 and 20, 1908, in the form of a jubilee.

It is further proposed that a fund be created to preserve the memory of the occasion of Dr. Chaillé's retirement from the medical department and to perpetuate his name. This fund is to be employed to establish a chair of physiology or a chair of hygiene in Tulane University, to be named after Dr. Chaillé. The alumni and friends of Dr. Chaillé are requested to send their contributions to Dr. Isadore Dyer, secretary and treasurer of the Chaillé Memorial Fund, P. O. box 778, New Orleans.

#### News Items.

**Changes of Address.**—Dr. William Edwin Park, from Sunbury, Pa., to New Milford, Susquehanna County, Pa.

**Geneva, N. Y., Medical Society.**—The regular monthly meeting of this society was held on Thursday, April 2d. The general topic for discussion was Tuberculosis.

**The Glens Falls, N. Y., Medical and Surgical Society** held its regular meeting on Thursday evening, April 2d. The paper of the evening was read by Dr. J. S. White, of South Glens Falls, on *The Borderline of Insanity*.

**The Iowa State Sanatorium for the Treatment of Tuberculosis** was opened on February 1st, with six patients. The sanatorium has accommodations for eighty patients and is under the direction of Dr. H. E. Kirschner.

**Charitable Bequests.**—By the will of Dr. John Ordronaux, who died recently at Glenhead, L. I., the Mary Hitchcock Hospital, of Hanover, N. H., receives \$6,000 for a free bed, and the Norton Hospital, of Taunton, Mass., receives \$6,000.

**Philadelphia Medical Examiners' Association.**—At a stated meeting held on Tuesday evening, April 7th, Dr. G. G. Davis delivered an address on *A Consideration of Heredia from the Viewpoint of Life Insurance*. The discussion was opened by Dr. L. J. Hammond.

**Buffalo, N. Y., Academy of Medicine.**—The regular meeting of the Section in Surgery was held on Tuesday evening, April 7th. The principal paper of the evening was read by Dr. Robert W. Lovett, of Boston, on *Acute Traumatic and Chronic Synovitis of the Knee*.

**Union County, N. J., Medical Society.**—The annual meeting of this society was held on Wednesday, April 8th, at the General Hospital, Elizabeth. Officers were elected for the ensuing year, and Dr. H. R. Livengood, the retiring president, read a paper on *Abdominal Pain*.

**Philadelphia Municipal Hospital Changes.**—Dr. Samuel S. Woody has been appointed chief resident physician, Dr. Edward K. Mitchell has been appointed third assistant resident physician, and Dr. Charles J. Swalm has been appointed second assistant resident physician.

**The Medical Society of the Borough of the Bronx.**—A stated meeting of this society was held on Wednesday, April 8th. The principal paper of the evening was read by Dr. William Seaman Bainbridge on *The Diagnosis and Treatment of Cancer—Some Practical Suggestions*.

**The Portland, Me., Medical Club** held a meeting on Thursday, April 2d. Dr. R. F. Goodhue presided, and Dr. W. H. Bradford read the paper of the evening on *Varicose Veins of the Lower Extremities with Resulting Varicose Ulcer*. Dr. P. W. Davis is the secretary of the club.

**The Hospital Ship "Relief,"** under the command of Surgeon Stokes, joined the fleet at Magdalena Bay on March 27th, where a number of sick men from different vessels were transferred to her. The *Relief* will remain with the fleet during the remainder of the cruise around the world.

**National Volunteer Emergency Service.**—The annual meeting of the National Volunteer Emergency Service Corps was held in New York on Tuesday evening, March 31st. Major General James Evelyn Pilcher is the director general of the service and Brigadier General Franclyn Elbert Davis is adjutant general.

**New York State Hospital for the Care of Crippled and Deformed Children.**—The bill recently introduced into the legislature providing an appropriation for the erection of a new building at West Haverstraw, N. Y., has been approved by the finance committee of the senate. It has already passed the assembly.

**No Yellow Fever in Cuba.**—Governor Magoon has received from Major Jefferson R. Kean the reports of twenty-six army surgeons in different parts of Cuba saying that there is no yellow fever in Cuba and that there is no need of further quarantine. The reports add that the health of the island generally is excellent.

**The Michigan State Society for the Prevention and Cure of Tuberculosis.**—This society was organized on February 21st at a meeting held in Detroit under the auspices of the National Association for the Study and Prevention of Tuberculosis, for the purpose of carrying on active work against tuberculosis.

**The Pathological Society of Philadelphia** held a stated meeting on Thursday evening, April 9th. The programme included the following papers: *The Production of Deciduomata*, by Dr. Leo Loeb; *The Interpretation of the Venous Pulse*, by Dr. George Bachman; *Volume and Specific Gravity of Organs Removed at Autopsy*, by Dr. Sydney L. Olsho.

**Medical Society of the County of Richmond, N. Y.**—The regular monthly meeting of this society was held on Wednesday evening, April 8th, at the Staten Island Academy of Medicine. Dr. Eugene J. Callahan read a paper on *Malignant Growths in the Spleen*, and Dr. Carl R. Keppler, of Manhattan, exhibited an apparatus used in the treatment of deformities.

**A Portrait of Dr. Packard Presented to the Pennsylvania Hospital.**—The former resident physicians of the Pennsylvania Hospital presented to the hospital a portrait in oil of the late Dr. John H. Packard, for many years chief surgeon of the institution. The presentation was made on March 27th in the presence of the entire staff of nurses and physicians now connected with the hospital.

**The Lake Keuka, N. Y., Medical and Surgical Association.**—The ninth annual session of this association will be held at Grove Springs, Lake Keuka, N. Y., on July 9th and 10th. The membership of the association includes physicians from the counties of Allegheny, Chemung, Livingston, Monroe, Ontario, Steuben, Schuyler, Seneca, Tioga, Wayne, Wyoming, and Yates. Dr. Lewis W. Rose, of Rochester, is the president of the association.

**Craggs's Research Prize.**—The London School of Tropical Medicine announces that a prize of £50 will be awarded to the student, past or present, of the school who, during the current year (October to October), makes the most valuable contribution to tropical medicine. If the work has already been published it will not be disqualified on that account. All contributions must be in English, and must be sent in on or before October 1, 1908. Further information may be obtained from the Medical Superintendent of the London School of Tropical Medicine, Royal Albert Dock, E. London.

**The Northwestern Medical Society, Philadelphia.**—At a stated meeting of this society, which was held on Monday evening, April 6th, the programme included the following papers: Dr. David L. Edsall, Our Present Knowledge of Autointoxication; Dr. John T. Carpenter, Ocular Complications of Toxæmia; Dr. Barton Cook Hirst, The Toxæmias of Pregnancy and the Puerperium; Dr. Alfred Stengel, The Treatment of Constitutional Toxæmias.

**The Detroit Academy of Medicine** celebrated its fortieth anniversary on February 25th. Five of the original thirteen members are still alive, and one of them, Dr. A. B. Lyons, was present at the meeting and gave a brief address on the early work of the academy. Dr. Leartus Conner reviewed briefly the life and work of each of the deceased charter members, and personal reminiscences of the eight deceased members were given by members of the academy.

**Northern Medical Association of Philadelphia.**—At a meeting of this association held on Friday, April 10th, the evening was devoted to a "symposium" on diseases of the rectum. Dr. Ernest La Place read a paper on the Diagnosis and Treatment of Malignant Diseases of the Rectum. Dr. Collier F. Martin read a paper on the Diagnosis and Treatment of Hemorrhoidal Disease. Dr. J. Coles Brick read a paper on the Diagnosis and Treatment of Ischiorectal Abscess and Fistula.

**Contagious Diseases in Chicago.**—According to the weekly bulletin of the Department of Health, the following cases of contagious diseases were reported during the week ending March 28, 1908: Diphtheria, 105 cases; scarlet fever, 84 cases; measles, 205 cases; chickenpox, 56 cases; typhoid fever, 20 cases; whooping cough, 39 cases; tuberculosis, 56 cases. Diphtheria showed an increase of 30 cases over the preceding week, measles showed an increase of 73 cases, and scarlet fever a decrease of 15 cases.

**The German Röntgen Society.**—In connection with the fourth congress of this society, which is to be held in Berlin on April 26th, there will be a Röntgen tube exposition. This exposition will demonstrate the historical development of the Röntgen tube and will give an exhibit of the various kinds of tubes in use at the present time, but will not show any of them in action. Further information concerning the exhibition may be obtained from Dr. Melzer, Langenbeck Haus, Berlin N., Germany.

**Syracuse, N. Y., Academy of Medicine.**—At a meeting of this academy which was held on Tuesday evening, April 7th, the programme included the following papers: Resection of the Humerus Following Gunshot Wounds, by Dr. F. H. Flaherty; Sporadic Cretinism, by Dr. W. H. Maynard; Tumor of the Pituitary Body, by Dr. F. W. Marlow; Puncture of the Heart with Suicidal Intent, by Dr. H. L. Elsner. Dr. Frederick W. Sears is the president of the academy and Dr. Clarence E. Coon is the secretary.

**Personal.**—Dr. A. A. Michelson, professor of physics in the University of Chicago, has been elected an honorary member of the Royal Irish Academy.

Dr. Theobald Smith, professor of comparative pathology at Harvard University, has been elected an honorary fellow of the Society of Tropical Medicine and Hygiene of London.

Dr. M. G. Varian, of Coram, Cal., is registered at the Philadelphia Polytechnic and College for Graduates in Medicine.

**The Philadelphia Academy of Surgery** held a stated meeting on Monday evening, April 6th. Dr. A. P. C. Ashlund reported a case of nerve anastomosis and anastomosis of tendon transplantation for infantile paralysis. Dr. J. J. A. Van Kaathoven read a paper on Twenty-five Hundred Cases of Gas Ether Anesthesia Without Complication. Dr. Charles H. Frazer read a paper entitled The Surgical Treatment of Trifacial Neuralgia, including a Series of Nucleon Intracranial and Tendon Extracranial Operations, with One Death.

**The Medical Association of the Greater City of New York.** A stated meeting of this association will be held in the Bon Hall, New York Academy of Medicine, on Monday, April 13th, at 8:30 p. m., for which the following programme has been arranged: Dr. Robert Coleman Kemp will read a paper on Various Clinical Types of Acute Phla-

tation of the Stomach; Dr. Samuel G. Gant will read a paper entitled An Efficient Method of Irrigating the Small and Large Intestines; Dr. H. Beekman Delatour will report three cases of perforating ulcers of the alimentary canal; and Dr. A. Ernest Gallant will give a demonstration of a corset for visceral ptoses. Among those who will participate in the general discussion are Dr. William H. Thomson, Dr. Max Einhorn, Dr. Joseph Merzbach, Dr. Jacob Kaufmann, Dr. Martin L. Bodkin, and Dr. Ludwig W. Kast.

**The Health of Pittsburgh.**—During the week ending March 21, 1908, the following cases of transmissible diseases were reported to the Bureau of Health of Pittsburgh: Chickenpox, 13 cases, 0 deaths; typhoid fever, 31 cases, 6 deaths; scarlet fever, 18 cases, 1 death; diphtheria, 9 cases, 2 deaths; measles, 172 cases, 3 deaths; whooping cough, 26 cases, 2 deaths; pulmonary tuberculosis, 27 cases, 13 deaths. The total deaths numbered 182 in an estimated population of 403,330, corresponding to an annual death rate of 23.46 in 1,000 of population.

**Rochester, N. Y., Academy of Medicine.**—The regular monthly meeting of the Section in Surgery, which includes anatomy, orthopaedic surgery, ophthalmology, otology, laryngology, dermatology, and genitourinary surgery, was held on Wednesday evening, April 8th. Dr. Floyd S. Winslow reported a case of retention of urine complicating pregnancy, and two cases of tuberculous peritonitis, and Dr. Milton Chapman reported a case of skin grafting. Dr. J. W. McGill is the chairman of the section and Dr. Curtiss Jameson is the secretary.

**New York Academy of Medicine.**—A public meeting will be held in Hosack Hall on Thursday, April 30th, at 8:30 p. m. The Hon. Rufus B. Coving will deliver an address on the Value of Medical Expert Testimony, based on an experience of twenty-eight years on the bench. He will be introduced by Dr. John A. Wyeth, president of the academy, who will make a brief introductory address. At this meeting the president and the members of the State and New York City Bar Associations will be invited to meet the fellows of the academy and the medical profession at large.

**Registration of Tuberculosis Cases in the District of Columbia.**—A bill has been passed by the House of Representatives providing for the registration of all cases of tuberculosis in the District of Columbia, for the free examination of the sputum of suspected cases, and for other measures that will aid in preventing the spread of tuberculosis in the district. This bill will in all probability become a law, and Washington will then have a very comprehensive ordinance covering the question of the registration of tuberculosis.

**The Medical Society of the County of Ontario, N. Y.**—The quarterly meeting of this society will be held in Canandaigua on Wednesday, April 15th, at 2 p. m., in the Y. M. C. A. building. The tuberculosis exhibit of the State Department of Health will be in the building and will be open to the public all day. The programme includes the following papers: The General Practitioner in the Fight Against Tuberculosis, by Dr. F. L. Stebbins; Myocardial Changes with Fleeting Physical Signs, by Dr. H. L. Elsner, of Syracuse; Tuberculosis, by Dr. H. D. Pease, of Albany. Dr. C. P. W. Merritt, of Clifton Springs, is the president of the society, and Dr. D. A. Eiseline, of Shortsville, is the secretary.

#### Infectious Diseases in New York:

*We are indebted to the Bureau of Records of the Department of Health for the following statement of cases, deaths and deaths reported for the two weeks ending April 4, 1908.*

	March 28.		April 4.	
	Cases.	Deaths.	Cases.	Deaths.
Tuberculosis pulmonary	113	2	145	10
Diphtheria	105	2	105	11
Measles	205	12	205	11
Scarlet fever	84	4	90	1
Small pox	—	—	—	—
Whooping cough	39	—	39	—
Cholera infantum	1	1	1	1
Whooping cough	1	—	1	—
Unidentified	1	2	1	1
<b>Totals</b>	<b>440</b>	<b>21</b>	<b>490</b>	<b>24</b>

**Scientific Society Meetings in Philadelphia for the Week Ending April 18th.**—*Monday, April 13th.* Section in General Medicine, College of Physicians; Wills Hospital Ophthalmic Society. *April 14th,* Philadelphia, Paediatric Society; Botanical Section, Academy of Natural Sciences. *April 15th,* Philadelphia County Medical Society (business meeting for members only); Section in Otology and Laryngology, College of Physicians; Association of Clinical Assistants, Wills Hospital; Franklin Institute. *Thursday, April 16th,* Section Meeting, Franklin Institute; Medical Society of the Woman's Hospital; Section in Ophthalmology, College of Physicians. *Friday, April 17th,* University of Pennsylvania Medical Society; American Philo-sophical Society.

**The Mortality of Chicago.**—According to the report of the Department of Health for the week ending March 28, 1908, there were during the week 660 deaths from all causes, 381 males and 281 females, corresponding to an annual death rate of 15.89 in 1,000 of population. In the corresponding period for the year 1907 there were reported 744 deaths from all causes, and the annual death rate was 18.40. The principal causes of death were: Apoplexy, 19; Bright's disease, 37; bronchitis, 25; consumption, 83; cancer, 28; convulsions, 6; diphtheria, 8; heart diseases, 51; influenza, 5; intestinal diseases, acute, 34; measles, 4; nervous diseases, 33; pneumonia, 104; scarlet fever, 8; suicide, 8; typhoid fever, 7; violence (other than suicide), 32; whooping cough, 4; all other causes, 164.

**The Health of Philadelphia.**—During the week ending March 21, 1908, the following cases of transmissible diseases were reported to the Bureau of Health of Philadelphia: Malarial fever, 2 cases, 0 deaths; typhoid fever, 96 cases, 15 deaths; scarlet fever, 89 cases, 6 deaths; chicken-pox, 36 cases, 0 deaths; diphtheria, 103 cases, 13 deaths; cerebrospinal meningitis, 3 cases, 1 death; measles, 292 cases, 5 deaths; whooping cough, 13 cases, 5 deaths; pulmonary tuberculosis, 115 cases, 65 deaths; pneumonia, 77 cases, 76 deaths; erysipelas, 11 cases, 1 death; puerperal fever, 7 cases, 7 deaths; tetanus, 2 cases, 0 deaths; mumps, 23 cases, 0 deaths; cancer, 21 cases, 25 deaths. The following deaths were reported from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 10; diarrhoea and enteritis, under two years of age, 12. The total deaths numbered 531 in an estimated population of 1,532,738, corresponding to an annual death rate of 18.00 in 1,000 of population. The total infant mortality was 115; under one year of age, 87; between one and two years of age, 28. There were 38 stillbirths; 19 males, and 19 females.

**Meetings of Sections of the New York Academy of Medicine.**—The Section in Neurology and Psychiatry will meet on Monday, April 13th, at 8:30 o'clock. Dr. Wolff Freudenthal will present two patients showing peculiar paralytic affections of the larynx. Dr. H. W. Frauen-thal will report eleven cases of anterior poliomyelitis with involvement of the face, and will exhibit photographs of the patients. Dr. William B. Noyes will report a case of anterior poliomyelitis, with blood examination showing malarial parasite. Dr. Robert H. M. Dawbarn will read a paper on End Bearing Stump Comfort by the Aid of Shortening all Sensory Nerves at Amputation. Dr. Smith Ely Jelliffe will read a paper entitled The Psychiatrists and Psychiatry at the Age of the Cæsars.

A meeting of the Section in Public Health will be held on Tuesday evening, April 14th, at 8:15 o'clock. The Hon. Robert W. Heberd, Commissioner of Charities of New York, will read a paper entitled The Need of Additional Facilities for the Care of the Tuberculous Sick in This City. Among those who will take part in the discussion are Dr. John S. Billings, Jr., Dr. Alfred Meyer, Dr. C. M. Cauldwell, Dr. J. A. Miller, Dr. Henry L. Shively, and Dr. L. F. Frissell.

**American Therapeutic Society.**—The ninth annual meeting of this society will be held at the Bellevue-Stratford Hotel, Philadelphia, on May 7th, 8th, and 9th. The preliminary programme, which has just been issued, shows a long list of papers covering a wide range of subjects, and the meeting promises to be one of unusual interest. The presidential address will be delivered on Thursday morning by Dr. John V. Shoemaker, on Therapeutics in the Lighted Future. The Thursday afternoon session will be devoted to a "symposium" on diseases of the vascular system, and in the evening a joint meeting of the American Therapeutic Society and the Philadelphia Branch of the

American Pharmaceutical Association will be held, which will be followed by a reception. The morning session on Friday will be taken up with a discussion of the treatment of tuberculosis, and for the afternoon session the programme shows a list of thirteen papers on subjects of interest to the general practitioner. On Friday evening the president's reception will be held. On Saturday the general subject for discussion at the morning session will be Röntgen ray therapy, and the afternoon session will be devoted to routine business. The annual banquet of the members will be held on Saturday evening. The officers of the society are: President, Dr. John V. Shoemaker, of Philadelphia; first vice president, Dr. Joseph E. Janvrin, of New York; second vice president, Dr. Frederic H. Gerrish, of Portland, Me.; third vice president, Dr. Howard Van Rensselaer, of Albany; secretary, Dr. Noble P. Barnes, of Washington, D. C.

**The Regulation of Lying-in Hospitals in Ohio.**—A bill has been passed by the Ohio State Legislature regulating the establishment and maintenance of private lying-in hospitals, boarding houses for infants, and similar institutions. According to the provisions of the bill, particulars of which we glean from *Charities and the Commons*, no one is allowed to receive women for childbirth or board two or more children without a license from the State Board of Health. The application for the license must bear the approval of the local board of health. The license shall be for a term not exceeding one year. It must specify the number of women and infants who may be received. The State Board of Health and the local board of health may inspect the premises at any time, and may revoke the license at any time. All patients in such licensed institutions must be attended by legally qualified physicians. Complete records of all women or children received must be kept by each person holding the license. No child under two years of age from any such place shall be given out for adoption, except with the consent of a charitable organization, society, or institution having the care of children, duly incorporated, or by a juvenile court. No parent or guardian shall give an infant under the age of two years to any person for the purpose of placing it under the permanent care and control of any person for hire, gain or reward, but this provision shall not apply to any charitable institution, society, or association, or to its agents. No person holding a license shall advertise that he will adopt children or hold out inducements to parents to part with their offspring. Violations of the provisions of the act are misdemeanors, punishable by a fine of not more than \$500, or by imprisonment for a year, or both.

#### Society Meetings for the Coming Week:

**MONDAY, April 13th.**—New York Academy of Medicine (Section in Neurology and Psychiatry); Society of Medical Jurisprudence, New York; New York Ophthalmological Society; Society of Alumni of St. Mary's Hospital, Brooklyn; Corning, N. Y., Medical Association; Waterbury, Conn., Medical Association.

**TUESDAY, April 14th.**—New York Academy of Medicine (Section in Public Health); Medical Society of the County of Schenectady, N. Y.; Practitioners' Club of Jersey City, N. J.; Medical Society of the County of Rensselaer, N. Y.; Buffalo Academy of Medicine (Section in Medicine).

**WEDNESDAY, April 15th.**—New York Academy of Medicine (Section in Genitourinary Diseases); New York Society of Dermatology and Genitourinary Surgery; Woman's Medical Association of New York City (Academy of Medicine); Medicological Society, New York; New Jersey Academy of Medicine (Jersey City); Buffalo Medical Club; New Haven, Conn., Medical Association; New York Society of Internal Medicine; Northwestern Medical and Surgical Society of New York.

**THURSDAY, April 16th.**—New York Academy of Medicine; German Medical Society, Brooklyn; Newark, N. J., Medical and Surgical Society; Æsculapian Club of Buffalo, N. Y.

**FRIDAY, April 17th.**—New York Academy of Medicine (Section in Orthopaedic Surgery); Clinical Society of the New York Post Graduate Medical School and Hospital; East Side Physicians' Association of the City of New York; New York Microscopical Society; Brooklyn Medical Society.

## Pith of Current Literature.

### THE BOSTON MEDICAL AND SURGICAL JOURNAL.

April 2, 1908.

1. Intussusception: A Review of Some Recent Literature, with a Report of Cases, By JAMES S. STONE.
2. Remarks Upon Intussusception, with a Suggestion for a New Method of Operation Upon Cases in Which Reduction is Not Possible, By E. A. CODMAN.
3. Anomalous Folds in the Nasopharynx, By J. PAYSON CLARK.

2. **Intussusception.**—Codman observes that all cases in infants and children, in which the diagnosis can be made and which are not already very feeble, should be given one forcible oil enema under an anæsthetic on the operating table. This should be followed by laparotomy, whether the tumor disappears or not. Before using efforts at reduction forcible enough to cause increased shock, the surgeon should, if he does decide on it, make up his mind to carry out reduction up to the limit of the patient's strength. If reduction is considered too doubtful, resection with double enterostomy is the choice when (a) the mass is wholly composed of small intestine; (b) when it is wholly composed of large intestine and the mechanical conditions make resection easy. If reduction is abandoned and the mass is wholly composed of large intestine, and resection cannot readily be performed, excision of the intussusceptum is indicated by Barker's or Mikulicz's method. In irreducible cases in which the small intestine is invaginated into the large, simple enterostomy without resection and resection of the mass should be abandoned and replaced by ligation of the impacted mesentery and enterostomy. In infants where there is already evidence of severe exhaustion, ligation and enterostomy could probably be done very rapidly and with less operative shock than even a successful reduction, provided the operator from the beginning abandoned any idea of reduction. The essential object of the operation which is here suggested is to produce gangrene of the intussusceptum in a convenient manner, so that within a few days enough softening of the constricted portion will have taken place to allow of its ready reduction by gentle traction. When the arterial supply is cut off it cannot be long before the blood and œdema in the intussusceptum will be squeezed out by the peristalsis of the intussusciptens, leaving the submucosa still strong enough to stand a gentle pull. The suggestion is offered particularly for desperate cases to replace resection and hopeless effort at reduction. It would be easier, quicker, and produce less shock than any other form of operation.

### THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

April 1, 1908

1. The Ethics of Surgery, By CHARLES W. OVLAND.
2. The Treatment of Iritis, By E. C. ELLETT.
3. Treatment of Ulcers of the Cornea, By H. BERT FOLEY.
4. Alimentary Intoxication, By WILLIAM J. BUTLER.
5. Restoration of the Pelvic Floor, By HOWARD HILL.
6. Subacute Combined Cord Degeneration with Report of Cases, By J. J. GOSSELINK.

2. **The Treatment of Iritis.**—Ellett recalls to our mind Bradley and Stevenson's words in reference to the treatment of iritis, that the object of

treatment of iritis should be: To dilate the pupil, to relieve pain; to treat any constitutional condition that may be present as a cause. To dilate the pupil we must use a mydriatic drug, and atropine, four grains solution to the ounce, would be the best. In patients presenting themselves for treatment with adhesions already formed, it may be necessary to increase the strength to eight grains to the ounce for a few instillations in order forcibly to break up the adhesions. On the other hand, in children, and in those susceptible to the drug, a weaker solution may be expedient. Under some circumstances a small solid crystal of atropine may be introduced. In general four instillations in twenty-four hours, with the patient at rest, and under favorable surroundings, will suffice to keep the pupil dilated. When the patient is first seen it is well for the surgeon to instil the drops until the pupil is dilated, but we frequently see that very little dilation is procured in one hour, while a continuation of the drops for twenty-four hours may break all the adhesions and give a round pupil. Even if this has not happened by the end of the twenty-four hours, it does not mean that the adhesions are permanent, for continued use of the drug may result in the continued rupture of synechia for as long as four or five days. When full dilation is secured, the frequency of the instillation should be reduced until the minimum dose which will maintain the mydriasis is ascertained. Briefly, this should be continued until the eye is free from redness. The state of the pupil and the comfort of the patient together guide us in forming an idea of how satisfactory is the progress of a case of iritis. The use of the mydriatic, cocaine, dionine, rest, protection from light, and the application of heat or cold, all contribute to the patient's comfort and freedom from pain, and while pain persists improvement is not imminent. Special consideration should be given to one or two of these measures. Dionine is much used as an ocular analgesic. In many cases the instillation of a 5 per cent. or 10 per cent. solution will relieve ocular pain for several hours, and it may be repeated as often as necessary. Continuous dry heat of lesser degree is often soothing. Cold applications seem to be of the most value in traumatic cases, with threatened or feared suppuration. In such cases the application should be continuous as long as it is needed at all. It occasionally happens that a patient with ordinary plastic iritis prefers the effect of cold to that of heat, in which case cold may be used continuously or intermittently. We must often give anodynes internally. The various preparations of opium are most effective, but unpleasant by reason of the systemic disturbances to which they give rise. A mixture of antipyrine and sodium salicylate in moderate doses is a very efficient anodyne, five grains of the former and seven and one half of the latter in simple elixir being a convenient form and dosage. Constitutional treatment is essential and includes attention to every constitutional condition that can in any way retard the cure or interfere with the action of remedies. Aside from its relation to cause, internal treatment is of importance, and mercury and the salicylates are of great value in other forms than the syphilitic and rheumatic. Ellett has not had a very favorable

impression of the value of the iodides except in chronic cases or in cases associated with chorioiditis and running a slow course; nor does he find sweats so effective as in chorioiditis and general uveitis, though they are of decided value, as Woodruff and Woods have shown. Burnham's "combined method" of the use of mercury, iodides, and pilocarpine is considered by him well worthy of a trial.

4. **Alimentary Intoxication.**—Butler says of the treatment that it consists in combating the collapse, cutting short the intoxication, and slowly bringing the child back to a diet commensurate with its caloric requirements. The first indication may be met by hypodermoclysis of salt solution, using 50 to 100 c.c., and repeating as is deemed necessary. The second indication is met by withdrawing the food entirely and allowing water only for twenty-four hours. With the subsidence of all symptoms, begin feeding as follows: As exceedingly small quantities of fat are injurious, begin with centrifugated breast milk, if possible, given in teaspoonful doses, five times a day, or an equal quantity of buttermilk, to which neither sugar nor meal has been added; or, if this is not at hand, fat free milk may be used. As a diluent, and to supply the liquid necessary, water and a thin cereal gruel may be used or given separately. After an interval of twenty-four hours, provided treatment has been well tolerated, without any evidence of return of the intoxication, the separate quantities of milk may be increased to two teaspoonfuls, which, after two or three days may, under the circumstances mentioned, be doubled, and so on, until they are gradually brought to a diet (free of fat in artificially fed infants) that will temporarily meet their needs from a caloric standpoint, having added, in the meantime, with their increased tolerance of the buttermilk (where employed), 30 grammes of sugar, preferably maltose, and 15 grammes of flour to each litre of buttermilk while boiling. The child should not be kept on the buttermilk diet longer than six weeks. After this time whole milk dilutions will be necessary to meet its needs. In case the infant was at the breast, after four or five days of careful feeding with centrifugated breast milk, it may be returned to the breast, the amount of milk being carefully controlled. During the treatment slight relapses are common where the food toleration has been passed. More effective and permanent results are accomplished by proceeding slowly, allowing forty-eight hours for judging the effect of a food increase before again adding to it. Cathartics and intestinal antiseptics are unnecessary, unless constipation exists, as sometimes occurs in the soporose form, when a laxative is indicated. There is little doubt that injudicious dieting and constant or frequent administration of laxatives in convalescence are responsible for the persistence of varying temperature rises in the first instance, and slimy green stools in the second instance, which are wrongly interpreted as manifestations of an enterocolonic catarrh, or a bowel infection with repeated reinfections, etc.

#### 1. The Deep Intraocular Lesions of Infantile Inherited Syphilis and Tardy Inherited Syphilis.

—Bull, in speaking of therapeutics, remarks that his question is a broad one and beset with difficulties, which vary with the age of the patient, and especially when we come to consider the question of submitting the parents to continued observation and treatment. In the case of the patient, the indication for specific treatment seems to exist in all cases where there are lesions of possibly syphilitic origin, especially if one or more undoubted stigmata are present. In infants and very young children a proper dietary is very necessary, especially of the supporting kind, for these children need soups or meat extracts at an earlier age than other young children. A mild mercurial ointment acts very well in the cases of infantile iritis, in promoting absorption and assisting to break up the adhesions to the lens capsule. The prognosis as to resulting vision will depend largely on the possible existence of chorioretinitis, vitreous opacities, and lesions of the retina and optic nerve. But these cases of syphilitic lesions of the deep structures of the eye promise much more to persistent and careful specific treatment than is usually supposed. Dr. Bull cites Fournier, who lays down four propositions: 1. Specific treatment is indicated in all cases in which the patients are actually affected by lesions or symptoms which might be due to syphilis, and who show at least one of the stigmata mentioned. 2. If a patient shows one or more of the stigmata mentioned, he should be subjected to specific treatment as a prophylactic measure, even if there be no actual lesion present. 3. In a recognized syphilitic family, if a child has recently been born who presents one or more of the stigmata, the parents should be submitted to prolonged specific treatment, in order to prevent, if possible, the transmission of the inherited taint to any future births. 4. In case a woman becomes pregnant in a family in which the children previously born show some of the stigmata above mentioned, she is to be subjected to rigid specific treatment during her entire pregnancy. In view of the many serious, even disastrous, lesions which have come under his observation, Dr. Bull adds a fifth proposition to the four of Fournier, viz., that it should be made a penal offense for any syphilitic to marry.

3. **Acute Lobar Pneumonia.**—Dickinson remarks that the time necessary for the formation of sufficient opsonin, agglutinin, and antibodies to enable the phagocytes to accomplish their result is the length of the disease process proper. The crisis of the disease occurs at that time when these substances obtain the upper hand. Such is Nature's method of cure, and without this process, without the opsonins, or the agglutinins to assist the phago-

cytic action and the antibodies, the crisis does not occur and death may and probably does follow. As soon as the crisis has occurred, as soon as the battle has been fought and won by Nature, then comes the process of elimination of the different toxoids in the blood and the absorption of the pneumonic exudate and its elimination. This process of absorption is heterolysis—that is, the mutual fermentive action of one extraneous product upon another in the presence of leucocytes and electrolytes leads to their softening and the gradual passage through the lymphatic system into the blood. During pneumonia the sodium chloride output is diminished and often absent, because of its retention in the system, no more in the lung than elsewhere; nevertheless, its presence in the lung is of vast importance. Sodium chloride is an active electrolyte and easily becomes ionized. The electrolytes put life into the proteids, and without their presence active tissue changes would not occur. As soon as the crisis has passed we have the nitrogen output increased and sodium chloride in proportion, while the leucocytes promptly diminish in number. In addition to the local effect of the germ mighty influences are brought to bear in various ways upon the economy in general. After one or two days' intubation, tissue and microbic poisons, of amount sufficient to produce fever, rapidly accumulate. The sudden influx into the system of these materials produces a vasomotor reflex disturbance so severe that the peripheral capillaries contract and the volume of blood is largely thrown into the abdominal cavity. This condition is clinically known as the chill or rigor. Although it is the first symptom ordinarily recognized, a careful study of individual cases, where possible, will show minor respiratory lesions, tonsillitis, indicative of pneumococcus invasion through the tonsil; tracheobronchitis, often induced by the pneumococcus, gastroenteritis suggestive of entrance by this means, or conditions of malaise, with rise in temperature. The supreme factor in treatment is the serum. Leucocytes, except in the very pathogenic types of pneumonia, do not fail, but the ferments peculiar to the serum, though present in the normal individual, require several days for their sufficient elaboration. All treatment therefore should be directed towards the prompt formation of these substances. The opsonins in particular are easily influenced by various conditions. Sleep and mental and physical comfort materially assist in their formation. A quiet, sympathetic, and attentive nurse, congenial surroundings, and the assurance of recovery are not unimportant factors for their formation. Vaccination after the plan of Wright with dead pneumococci obtained by culture from the pharynx is a logical procedure and has been reported as successful. It has been shown that several drugs ordinarily administered during the course of this disease are potential for harm. Alcohol, for instance, will quickly reduce the opsonic index. Another action of alcohol is that it is quickly absorbed from the stomach without being acted upon by the digestive fluids, and, passing into the liver, inhibits that organ's function as a toxine destroyer. Our best clinicians do not resort to it until the crisis, but even then it may be harmful, for, if there remain any pathogenic germs

in the lung with the opsonic index cut down too promptly, relapses may occur. Opium, aconite, and large doses of quinine inhibit the ameboid movements of the white blood corpuscles. Small so called "tonic" doses of quinine, however, have a contrary effect. Water should be given liberally for its flushing effect. As the pneumococcus brings about the formation of acids in the lung and catabolism of body acids in the tissues, some alkaline is valuable through the entire course of the disease; the ammonia preparations are perhaps the best type. They further tend to forestall heart clot.

1. Visible Signs of Visceral Disease, By J. GALLOWAY.
2. An Analysis of Two Hundred and Fifty-three Cases of Tabes, By B. BRAMWELL.
3. Remarks on the Treatment of Syphilis by Intramuscular Injections, By J. E. LANE.
4. A Case of Syphilis, Phthisis, and Locomotor Ataxia, By H. G. SUTHERLAND.
5. On Extragenital Syphilitic Infection, By H. BAYOU.

**1. Signs of Visceral Disease.**—Galloway's article deals with the cutaneous signs of liver disease, which signs he classifies as follows: 1. Eruptions of the type of erythema exudativum, occurring in cases of disease of the liver with portal obstruction, such as cirrhosis. Cutaneous manifestations of the erythematous type occur during the course of diseases of the liver, especially in those cases in which the portal blood passes into the general and therefore into the cutaneous circulation without being subjected to the normal cleansing action performed by the liver. (a) Urticaria. This is quite uncommon in liver disease, the circulating toxines tending to produce the allied eruptions of the erythema multiforme type. (b) Erythema exudativum. This is not uncommon in cirrhosis of the liver, occurring most profusely on the trunk as discs or as segments of circles. The irritation and pruritus may be intense. The attacks do not usually last more than ten days, but are apt to recur. The eruption is frequently complicated by jaundice. (c) Hæmorrhagic exudative erythema. Erythematous eruptions occasionally become purpuric, varying from a slight amount of blood staining to intensely hæmorrhagic lesions, occurring as elevated spots or patches having the color of a superficial hæmatoma. (d) Erythema leading to atrophy of the skin. This so called "lupus erythematosus" is entirely distinct from lupus vulgaris; there is no distinct relationship, and possibly only in some cases a remote connection with tuberculous diseases of other organs. The inflammation and exudation are of a peculiar type, leading to atrophy of the connective tissues and alterations in the character of the epithelium. 2. Dilatation of superficial blood vessels as an indication of diseases of the liver. Several forms of dilatation of the superficial veins occur: (a) A very striking type is the enlargement of the subcutaneous veins of the abdomen, forming collateral channels for the return of blood, with a general course from the groin upwards to the intercostal veins and even towards the axilla. These enlarged veins are evidences of obstruction to the vena cava rather than to the portal circulation. (b) Dilatation of venules is usually noted in one of two situations. First, those radiating from the umbilicus and permitting

blood to pass backwards from the liver through its round ligament into the subcutaneous veins of the abdomen. This occurs in cases of obstruction to the portal circulation arising in the liver itself, and permits of the passage of portal blood directly into the general circulation. The condition is known as "caput medusæ" or "cirsomphalos." Second, enlargement of the "costal fringe of venules" along the lower border of the thorax. This is not specially significant of hepatic disease. Third, indications occurring in the course of the lymphatic vessels. An early sign of cancer of the bile ducts and of the gall-bladder is the appearance of an indurated patch involving or in the immediate neighborhood of the umbilicus. Fourth, primary new formations in disease of the liver. Xanthoma. The majority of cases of the widely spread form of xanthoma are accompanied by important morbid changes of metabolism, especially associated with the functions of the liver. Fifth, anomalies of pigmentation as signs of visceral disease. (a) *Hæmochromatosis*. This is due to the destruction of red blood cells, with the formation and deposition of abnormal pigment throughout the body and in the skin. Most of the cases are associated with disease of the liver, and often with glycosuria. (b) *Jaundice*. This, of course, is the most common and most important of the indications of disease of the liver.

2. **Locomotor Ataxia.**—Bramwell has tabulated 263 cases of locomotor ataxia with the following results: 192, or 73 per cent., were in the ataxic stage, and 71, or 27 per cent., in the preataxic stage of the disease. 239, or 90 per cent., were males. In 73 per cent. of the cases the disease began between the ages of thirty and fifty years. In one case it began as early as at twenty-one years, and in another as late as at sixty-six years. One patient, aged seventy-three years, presented many symptoms of the disease, but had no lightning pains. 159, or 60 per cent. of the patients were married. In 155, or 61 per cent., the patients admitted having had syphilis, and in 12 per cent. more syphilis was doubtful. (No attempt was made to discriminate between "hard" and "soft" chancres.) In 45 per cent. of the syphilitic cases, the locomotor ataxia developed within ten years after infection. In only 10 per cent. did it develop more than twenty years after infection. In a few of the cases marriage seemed to have a decided influence either in producing or aggravating the disease. Alcoholic excess was admitted in about 10 per cent. Among the other causes assigned may be mentioned injury, exposure to cold and wet, lying out at night, mental worry, infectious diseases and lead poisoning. The first symptoms, as stated by the patient, were lightning pains in 51 per cent., diplopia in 7 per cent., dimness of vision in 7 per cent., and ataxia in 6 per cent. Lightning pains were by far the most frequent of all the symptoms and signs of the disease. Visceral crises of some form or another were present in 13 per cent. of the cases, the gastric being the most frequent form. Tropic lesions in the bones and joints occurred in 6 per cent. of the cases. In 11 per cent. of the cases general paralysis of the insane developed in the course of the locomotor ataxia. Seventy cases proved fatal, the most frequent cause of death being general paralysis of the

insane. The average duration of the fatal cases was 8.2 years (shortest under one year, longest twenty-two to twenty-three years).

1. Tuberculosis of the Kidney and Malignant Disease of the Cæcum (Lettgowian Lectures, I), By C. J. SYMONDS.
2. The Surgery of the Spinal Cord and Its Membranes (Hunterian Lectures, III), By D. J. ARMOUR.
3. Acquired Diverticula of the Sigmoid Flexure, Considered Especially in Relation to the Secondary Pathological Processes and Their Clinical Symptoms, By W. H. M. TELLING.
4. Preliminary Note on Some Aspects of Splenic Anæmia, By G. A. GIBSON.
5. A Case of Obstruction Caused by Sarcoma of the Small Intestine, By A. C. D. FIRTH.
6. Deaths Under Anæsthetics, By F. J. WALDO.

3. **Acquired Diverticula of the Sigmoid.**—Telling reports three instances of acquired diverticula of the sigmoid flexure. Diverticula may occur in any part of the intestine and are divided into two kinds, congenital and acquired. Meckel's diverticulum is the most familiar example of the first kind, but they may occur anywhere. Acquired diverticula are also found in almost any situation in the gut. They are generally thought to be most frequent in the large intestine, and especially in the lower part of the descending colon and the sigmoid flexure. In the latter location they are usually multiple, have fairly constant anatomical features, and are particularly liable to undergo secondary pathological processes, with a symptomatology peculiarly their own. The diverticula, apart from such secondary processes, do not give rise to symptoms or cause trouble. In the sigmoid flexure they occur mainly in two rows, either at the side of the gut or close to the mesenteric attachment, more rarely on the convexity. The commonest situation is into the epiploic appendices. In many cases they are confined to them and then generally present a double row of symmetrically placed, hollowed out "pockets." The special favoring of the epiploic appendices is ascribed to the fact that the point of their attachment to the gut is a point of least resistance. In a majority of cases the affected appendages are or have been filled with a large amount of fat. The diverticula vary in size, usually from mere macroscopic visibility to that of a hazel nut. A larger size is rarely attained, owing to secondary changes, which lead either to detachment, ulceration, abscess, or peritonitis. When small they are semiglobular, and as they increase they become more flask shaped. The following are the views held by various observers as to their etiology: 1. The generally advanced age of the patients. In eighty cases the average age was sixty years. 2. Sex. In eighty-one cases fifty-three were men. 3. Obesity. Certainly many of the patients have been fat. 4. Cachexia and absence of fat. Many subjects, on the other hand, are thin, after having been fat. The loss of fat is supposed to weaken the wall of the intestine. 5. The normal structure of the large intestine, which readily lends itself to local yieldings of its walls. 6. The physiological rôle of the sigmoid flexure—feces are retained longer in this part of the gut, and consequently the pressure is greatest. 7. Pressure from within the bowel, due to the accumulation of feces

or gas, or both, constipation and flatulence. 8. The relation of the diverticula to the points of entry of the vessels through the gut walls. 9. The variations in size of the vessels. 10. The connective tissue around the vessels. 11. Muscular deficiency of the gut wall. As the diverticulum enlarges, the earliest pathological change is an atrophy of the muscle layers, with the following serious results: (1) Thinning of the diverticulum wall. (2) Perforating action of the retained concretion. (3) The presence of microorganisms and their toxins. (4) Inflammatory reaction of varying type and degree. The secondary processes to which sigmoid diverticula are liable may be summed up as follows: (a) Infection of the general peritoneal cavity from thinning of the sac walls, without perforation. (b) Acute or gangrenous inflammation—"diverticulitis." (c) Chronic proliferative inflammation with thickening of the gut wall and stenosis of the bowel. (d) The formation of adhesions, especially of adhesions to the small intestine and to the bladder. (e) Perforation of the diverticula, giving rise to general peritonitis, general abscess, submucous fistulæ of the gut wall, and fistulous communication with other viscera, especially the bladder. (f) The lodgment of foreign bodies. (g) Chronic mesenteritis of the sigmoid loop. (h) Local chronic peritonitis. (i) Metastatic suppuration. (j) The development of carcinoma. (k) Perforation into a hernial sac.

6. Deaths Under Anæsthetics.—Waldo has endeavored to ascertain the exact facts regarding the mortality in Great Britain due to anæsthetics, and has examined the methods whereby statistics of the kind are officially presented to the registrar general. His conclusions are as follows: 1. That present available data as to deaths during anæsthesia are so imperfect as to be useless for the purpose of formal investigation. 2. That the returns of such deaths are for the most part obtained from coroners' returns of deaths occurring in hospital practice. 3. That only a small proportion of deaths under anæsthesia in private practice ever come to the notice of registrars or coroners. 4. That imperfect as are the returns for England and Wales, those of Scotland and Ireland are still less trustworthy. 5. That with such imperfect data it is impossible to form any trustworthy conclusions as to the absolute rate of fatalities to administrations, or to the relative proportions of deaths to deaths in the case of particular anæsthetic deaths. 6. That it is highly desirable to arrive at satisfactory conclusions as to the precise facts of all deaths under anæsthesia, both for the safety of the public and the furtherance of scientific knowledge. He therefore recommends: 1. That no general or local anæsthetic shall be administered by any but a duly qualified medical man, except in some exceptional circumstances, which shall be duly reported to some recognised official authority. 2. That full details be kept by the anæsthetist of all administrations of anæsthetics, whether in hospital or private practice, including date, time, and address of patient, an operator and of administrator, nature of operation, the drug used, and other pertinent details. 3. That a register of all administrations of anæsthetics be kept in all medical charities, poor law infirmaries, asylums, and

other public institutions. 4. That so far as possible special skilled anæsthetists be appointed to all hospitals and infirmaries, and that resident anæsthetists be provided in all the larger institutions. 5. That when the administration of an anæsthetic is intrusted to a junior qualified man, he should be supervised by a skilled anæsthetist, except where he can produce a certificate of special skill and experience as an administrator, or where a skilled anæsthetist is not available. 6. That notification be made to the coroner of all deaths occurring at any stage of general anæsthesia by the anæsthetist and other concerned. 7. That coroners be required to hold a public inquiry into all cases of death during anæsthesia, and that they make a detailed report to the registrar general, together with the verdict. 8. That a commission might with advantage be appointed to inquire into the present facts of deaths under anæsthesia, so far as may be ascertainable.

1. Laryngostomy. By SARGNON and BARLATIER.
2. Late Ocular Lesions After the Ophthalmoreaction with Tuberculin. By PAUL VAN DERME and EVARISTE STUCKE.
3. Compensatory Hypertrophies and Vascular Actions. By R. ROUME.

1. Laryngostomy.—Sargnon and Barlatier, in a brief historic sketch of this operation, say that it was first performed, to the best of their knowledge, by Professor Ruggi in January, 1898, but its merits were prominently brought forward by Killian in 1906. They describe the operation, which they divide into, 1, the operation itself; 2, the dilatation and the dressings; 3, the autoplasty; and, 4, the watching and the maintenance of a tracheal orifice. Two varieties are named, the typical tracheolaryngostomy and the total or partial laryngostomy. The indications for laryngostomy are laryngotracheal stenoses, in order that they may be dilated, and when there are no stenoses to permit inspection or treatment, such as dressings, caustics, phototherapy, radiotherapy, or curettage. The latter cases include those of malignant tumors in their early stages, certain forms of glottic and subglottic tuberculosis, certain forms of laryngeal paralysis, and recurrent papillomata of the larynx. It is specially indicated in cicatricial strictures. The contraindications are not numerous. The operation should not be performed when there is pus in the trachea, when there is fever, when there is a severe bronchitis, or when there is an obstacle in the trachea below the place where the canula would be, a papilloma, for example. The inconveniences are slight. After the removal of the canula the vocal troubles clear up, and they state that many of their patients sing. The results of the operation they consider very encouraging, and they believe that it furnishes a certain and definite cure for serious cicatricial stenoses otherwise incurable.

March 26, 1908.

1. General Hygiene in the Hygiene of Medicine at the Faculty of Medicine of Paris. By Professor GEORGES BASTET.
2. Statistics of the Bacteriological Microbiology of the Human and Animal Kingdom. By Professor J. G. THOMAS.

**2. Sporotrichosis of the Buccopharyngeal Mucous Membrane.**—Letulle pictures the condition of the mucous membrane of the mouth and pharynx produced by the *Sporotrichum Beurmanni* as well as the microscopical appearance of the spores. He alleges that the disease, both clinically and pathologically, is an affection *sui generis*, distinct in all points from any other ulcerative affection which has yet been described. It does not appear to be related even indirectly to tuberculosis or syphilis. If it should appear coincidentally with one of these diseases in the same patient the differentiation would always be absolute and precise.

#### BERLINER KLINISCHE WOCHENSCHRIFT.

March 9, 1908.

1. What Is the Cause of Death? By JOHANNES ORTH.
2. The Theory and Practice of the Serum Diagnosis of Syphilis, By FLEISCHMANN.
3. The Action of Sodium Oleate in Wassermann's Reaction of Syphilis, By HANS SACHS and KARL ALTMANN.
4. Concerning a Bilateral Isolated Luxation of the First Metatarsal Bone, By ALFRED STIEDA.
5. The Varieties of the Skeleton of the Human Foot, By W. BÖCKER.
6. Hyperæmia in the Treatment of Internal Diseases, By A. LEWANDOWSKI.

1. What is the Cause of Death?—Orth discusses this subject from the medical, scientific, and legal standpoints, but presents little, if anything, new.

2. Theory and Practice of Serum Diagnosis in Syphilis.—Fleischmann studied the effects produced by serum in 230 cases, 192 syphilitic, 38 nonsyphilitic. The thirty-eight control cases included cases of nonsyphilitic brain tumors, tuberculous meningitis, typhoid fever, pneumonia, sepsis, myelitis, apoplexy, and carcinoma. In all of these the reaction was negative. The syphilitic cases were divided into four groups: 1, Positive syphilitics, with positive syphilitic symptoms manifest at the time of investigation, eighty-nine cases; 2, positive syphilitics, without manifest symptoms at the time of investigation, sixty-four cases; 3, patients with symptoms suspiciously like syphilis and questionable former infection, thirty-two cases; 4, positive syphilitics, who presented symptoms of disease which could scarcely be ascribed to the former syphilis, seven cases. The eighty-nine patients who composed the first group presented at the time of investigation primary, secondary, tertiary, or the so called metasymphilitic symptoms. In these the serum gave a positive result in eighty-three, 93.5 per cent.; a negative in six, 6.5 per cent. The six negative cases were a case of tabes dorsalis of several years' duration, which had been repeatedly treated; another case of tabes dorsalis which had been under treatment for years, an untreated case of tabes dorsalis with a syphilitic history of twenty-eight years' duration, an ulcer of the nasal septum that had been treated for three years with inunctions and injections, an old syphilitic chorioiditis, and secondary papules in a patient during treatment. The first five were therefore cases in which the process had been long existent or exhausted, and in four had undergone specific treatment. The second group was composed of sixty-four patients, who presented no manifest symptoms, though conceded to have been infected with syphilis. A positive reaction was ob-

tained in thirty-three, 52 per cent.; a negative in thirty-one, 48 per cent. A comparison of these results with those obtained in the first group shows that the presence of symptoms is of considerable moment in the production of the reaction. The author suggests that in certain of these cases the presence of the reaction may be an indication for the renewal of treatment of the disease. In three of the cases that gave a negative result fresh syphilitic symptoms appeared some months later, and then the reaction was positive. The negative reaction tells us nothing. In the thirty-two cases of the third group one half gave a positive reaction, one half negative. No positive conclusion can be drawn as to the value or lack of value of the reaction in these cases, but in a considerable number the positive reaction was confirmed by the results of specific treatment, and the negative by the course of the disease. The fourth group comprised seven syphilitics who were suffering from probably nonsyphilitic skin affections. The reactions obtained were positive in one, negative in six. The author concludes that in spite of our ignorance in regard to the theoretical basis Wassermann's reaction has an extensive clinical application in the hands of careful investigators experienced in serological work. Its chief domain is in the cases in which suspicious symptoms appear while infection is denied or is uncertain. A positive reaction may be considered diagnostic in such a case, and a negative result, particularly in the absence of former treatment, may, under certain circumstances, be of value. In the second place the test may have a certain value in old cases which have presented no symptoms for a long time, and the question needs to be determined whether to renew treatment or not. A positive reaction might be an indication for such renewal of treatment, even though a negative result would not contraindicate it when suggested otherwise. The reaction does not appear to be useful for the diagnosis of cured syphilis.

#### MÜNCHENER MEDIZINISCHE WOCHENSCHRIFT.

March 17, 1908.

1. The Fluid in the Sound and the Diseased Conjunctival Sac, By SCHIRMER.
2. Destruction of Blood Plaques, Blood Clot, and Muscle Clot, By BÜCKER.
3. A New Stethoscope for Measuring the Subjective Strength of the Heart Beat, By BOCK.
4. The Treatment of Eclampsia, By OSTERLOH.
5. Comparative Studies with the Conjunctival Reaction of Wolff-Eisner and the Ointment Reaction of Moro, By HEINEMANN.
6. Concerning Disinfection of the Hands with Chirosofer, By BECKER.
7. More Favorable Experiences in the Treatment of Blennorrhæa of Adults with Blenolenicet Ointment, By ADAM.
8. Concerning the Relations Between Infant Mortality, Infant Nutrition, and Fitness for Military Duty, By HAHN.
9. Concerning the Ability to Live of Infants with Very Large Congenital Umbilical Hernias, By DURLACHER.
10. Concerning X Ray Momentary Exposures with the Apparatus Used, By GRÖDEL and HORN.
11. The Problem of Skin Electricity, By HARNACH.
12. Fulguration According to Keating Hart, By WIESNER.
13. Lysol and Creosol Soaps, By AHLFELD.
14. Yearly Report of the Out Door Department of the Surgical Clinic at Munich, By GEBELE.
15. Studies in Opsonins (concluded), By MUCH.
16. Obituary of Professor Ferdinand Petersen, By PEISTER.

2. **Destruction of Blood Plaques, Blood Clot, and Muscle Clot.**—Bürker says that his experiments show that the material that prevents, or at least delays, the destruction of the blood plaques and the coagulation of the blood is irritant to the muscles at a temperature of 20° C., the more so the greater the degree to which the destruction of the blood plaques and the coagulation of the blood is prevented. This material influences in like gradation the muscle rigidity at 40° C., in that the muscle contract much earlier and more energetically than the control muscles. But the most striking circumstance is that the muscles, although they finally exhibit all other signs of rigidity, remain transparent, while the control muscles always become whitish and completely opaque. All solutions used to preserve the transparent muscles remained clear, while the control solutions always became slightly cloudy. A final peculiarity mentioned is that these muscles remained transparent when placed in alcohol or formalin. The author finally draws two conclusions from his experiments: 1, That the lime salts are of importance not only for the destruction of the blood plaques and the coagulation of the blood, but also for the normal passing off of the coagulation of muscle; 2, that cloudiness of the muscle is not a necessary criterion of muscle rigidity.

3. **New Stethoscope.**—Bock describes a stethoscope with an apparatus connected with it for the purpose of registering the strength of the heart beats. The instrument is complicated and difficult to describe briefly.

5. **Comparative Studies with the Conjunctival Reaction of Wolff-Eisner and the Ointment Reaction of Moro.**—Heinemann finds that Moro's reaction is as useful in making the diagnosis in tuberculosis as Wolff-Eisner's, and has certain advantages over the latter. After the conjunctival test he observed conjunctivitis, which often afflicted the patient for two weeks, while the ointment reaction was always harmless and afflicted the patient in no way whatever. This he considers a noteworthy practical advantage.

9. **Large Congenital Umbilical Hernia.**—Durlacher reports a case in which a child was born with a very large inoperable umbilical hernia, and was still living at the end of two years and four months. The treatment given was the application of moist warm compresses. He discusses other reported cases, the natural tendency to contraction of the aperture, the prognosis, and treatment, but adds little if anything new.

10. **X Ray Momentary Exposures.**—Grödel and Horn present some beautiful x rays—teleroentgenograms, they call them—produced by exposures of 1/15 of a second, 1 second, and 2 seconds.

10. Personal Observations and Conclusions on the Treatment of Fractures, By D. C. MORIARTY.

1. **Recent Advances in Obstetrics.**—Cragin states that advance has been most marked along three lines: (1) Better knowledge of obstetric pathology, (2) better knowledge of the mechanical problem of delivery, (3) better procedure. Knowledge of obstetric pathology has made most distinct advance in the toxæmia of pregnancy, as shown by pernicious vomiting on the one hand and eclampsia on the other. In pernicious vomiting there is fatty and hydropic degeneration of the liver, which may be diffuse, while the kidneys show degeneration of the epithelium of the convoluted tubules. In eclampsia there are two clinical types, one in which the liver is greatly involved and the kidneys slightly, and the other in which the kidneys are chiefly affected and the liver slightly. Three varieties of lesions were found in livers which were studied, the area of degeneration in the lobules varying in each type. The nephritic type of eclampsia included (1) those who had suffered with nephritis, the eclampsia having aroused the old trouble; (2) those whose kidneys were previously healthy. Better knowledge of the mechanics of labor consists in noting carefully the relation between the foetal head and the maternal pelvis in the later months of pregnancy, also in the early correction of occiput posterior presentations. Better procedure is based upon better pathology and better mechanical knowledge.

2. **The Diagnosis of Early Pregnancy.**—McDonald divides the signs and symptoms of pregnancy into (1) those from the history, (2) breast signs, (3) signs on vaginal examination. Absence of menstruation may or may not be a significant sign. It is frequently present from other causes than pregnancy. On the other hand, a bloody discharge may occur during the first three months of pregnancy. Nausea and vomiting are common symptoms, but neither are they limited to early pregnancy. They are present in about half the cases of pregnancy. Sensitiveness in the breasts is usually felt within two months of conception, and by the end of that period the enlarged papillæ, and the changed areolæ of the breasts are manifest. The vaginal signs are purplish hue of the cervix, softening of the cervix, compressible isthmus, alterations in the size, shape, and consistency of the uterus, and intermittent contractions of the uterus. The last of these are present or may be excited throughout

pregnancy. None of the foregoing signs are constant. Their value chiefly consists in the confirmatory evidence which they add to other signs.

**3. High Rectocele After Perineal Repair.**—Dickinson states that the factors in the production of rectocele are: 1. Laceration or lack of tone in the fascia and muscles of the pelvic floor. 2. Injury to the muscular layers of the rectal wall, or defective activity of such layers. 3. Defects in conformation of the rectum, or in the axis of the rectal canal, or both. 4. Obstruction from rigor or irritability of the sphincter. The methods of study of the form and direction of the rectal and anal canals upon the living are as follows: 1. The rectum is distended with air, and viewed with specula in the knee chest or in the lithotomy posture with lowered head. 2. By digital touch. 3. By tracing tape or wire, the measurements and angles being plotted on a full size sketch. High rectocele after operation is to be prevented (1) by digital rectal examination of sèptum before anæsthesia, (2) by identification of the structures at operation, and high apposition, (3) by after care. Precautions after operation for bad cases are (a) three or four weeks in bed, (b) a daily soft movement of the bowels, (c) low intraabdominal tension for three months, (d) overcoming irritability or sensitiveness or undue rigor of the sphincter, and watchfulness against constipation.

By H. R. PHILLIPS.

**1. The Aortic Incompetence of Later Life.**—Broadbent mentions as causes of degenerative lesions producing aortic regurgitation in old age (1) senile degenerative change, (2) high arterial tension or constant strain on the valves and arch of the aorta, (3) severe intermittent strain on the valves from frequent and violent fluctuations in the blood pressure, (4) syphilitic aortitis, (5) rupture of a valve. The physical signs are sudden, short, and forcible pulse wave, high blood pressure, hypertrophy of the left ventricle with a diastolic murmur at the aortic cartilage, the aortic second sound being also present and indicating dilatation of the aorta. If the lesion is due to intermittent strain in an arduous occupation, mitral incompetence quickly follows, with cough, dyspnoea, cyanosis, enlarged liver, fullness of the veins of the neck, cedema of the legs, and

death from heart failure. Aneurysm is one of the possible consequences. Uræmic symptoms and angina pectoris may also be present. The prognosis is always unfavorable, sudden death being of frequent occurrence. When uræmic symptoms are present mercurial purgatives, diuretics, and iodides, with a purin free diet, are indicated. With anginoid symptoms the nitrites and morphine should be administered. Digitalis is indicated only in some of the cases in which compensation has failed.

**2. Appendicitis.**—Bishop thinks the widespread opinion that the usual symptoms of an acute attack of appendicitis should be the signal for an immediate operation is entirely erroneous, and he protests against such an opinion. The opinion that every surgeon or practitioner who does not at once attack it surgically is criminally negligent is similarly erroneous. If there is a history of two or three previous slight attacks, gangrene and perforation may be excluded. If acute perforation has occurred into a protected cavity and not into the general cavity of the peritonæum it had better be let alone. The rage for speed in operating is responsible for much bad work, and the rash and hasty breaking up of protective adhesions often leads to infection of the general peritonæum. During the acute stage the virulence of the microorganisms is at its highest, the development of opsonins and antitoxines is at its lowest. In cases in which there have been previous attacks it is therefore wise to defer operating until a quiescent period. In cases without a history it is frequently, but not always, best to operate at the earliest possible moment.

**3. Valvular Disease of the Heart.**—Crawford says of pulmonary stenosis that it is a rare lesion and may be congenital or acquired. Rheumatism, syphilis, and bacteria are causative in the congenital variety, rheumatism and other acute infective diseases in the acquired variety. It may exist (1) at the situation of the orifice and valves, (2) in the infundibulum of the ventricle, (3) in the artery of its main subdivisions. It quickly causes hypertrophy and dilatation of the right ventricle. Clinically one observes in such cases pallor, dyspnoea on exertion, and general debility. Some of the cases present marked symptoms of circulatory sepsis. The visible signs may be pulsation over the front of the heart and in the epigastrium, and in some cases præcordial bulging. The diagnosis rests upon the presence of a systolic murmur in the second left interspace, moving upward and outward, accompanied by a thrill. The second sound is diminished or reduplicated, and the right ventricle shows hypertrophy or dilatation. Sufferers with this condition are very susceptible to tuberculosis. As to treatment, bronchial catarrh must be avoided, a dry and warm climate must be selected, and great exertion must be avoided. In general, the treatment must be symptomatic, on the lines applicable to cardiac failure.

**6. Rupture of the Genital Canal.**—Hicks thinks this accident should be classified as intra and extraperitoneal, rather than as complete and incomplete. The latter is simple as to treatment and prognosis compared with the former. Intraperitoneal rupture may be (a) spontaneous and without delivery of the fetus, or (b) with delivery of the fetus and fol-

lowing version or other forcible manipulation. The former is usually unavoidable, rupture occurring at the point of greatest pressure, its direction being transverse to the line of greatest tension. It is generally behind and vertical in the vagina and oblique or transverse in the lower uterine segment. It is almost always at the cervicovaginal junction, extending upward and downward. The abdomen must be opened if foetus and placenta have entered the peritoneal cavity. The rent should be sutured, the peritoneal cavity shut off from the uterine cavity, and the latter drained. Bleeding must be checked by ligation of bleeding vessels or the tissues through which they are passing. Wounds of the bladder should be ligated. In cases in which suturing of the uterus is inadvisable a gauze drain should pass from the rent to the vagina. Internal version and transverse presentation cause most of the ruptures in which the foetus has been delivered. The rent may not be discovered for hours after its occurrence. Irrigation and drainage with gauze constitute the treatment. One must not forget the possible development of abscess in the torn and bruised tissues.

1. The Purification of Drinking Water for Troops in the Field.—Darnall describes his apparatus. It consists of a galvanized iron tank or can 24 inches high with an oval section measuring 7 by 16 inches; two cylindrical water cans 7 by 22 inches, with a mark indicating the three-gallon point; and a filter consisting of a cylindrical metal framework, connected to a siphon of one half inch galvanized water pipe. The short limb of the pipe is closed at the end, but communicates with the interior of the framework of the filter. The long arm is provided with a stopcock. Over this cylindrical framework the filtering medium is wound and fastened in such a manner that water must traverse the filter to gain access to the short limb of the siphon. The filtering material is a cotton fabric known as "outing flannel," and is quite closely woven. About twenty-eight thicknesses are used after being folded into a suitable size and sewed together. This material met the requirements better than any other that was tried. It gives a large flow of water, is easily sterilized, and does not shrink. Such a siphon weighs about twelve pounds and will deliver about fifty-five gallons of water per hour. To start the siphon action, a small pump somewhat like a bicycle pump is used. The apparatus is so constructed that all parts may be packed in the large oval can which is then placed in a light wooden crate. This crate is also used for a stand for the filter. This filter complete weighs about thirty-five pounds without the crate which, on occasion, may be dispensed with.

By leaving out the water cans, the weight may be further reduced to twenty-six pounds. By distributing the parts among several men it can be easily transported by marching troops. In operating this form of apparatus "hydroxid powder" is used, a one-pound tin of this being sufficient for 500 gallons of water. The powder consists of alum and soda, mixed in the form of a powder. The method of operation is simple. The filter cloths, of which there are several, are all sterilized by boiling in the morning before starting and one is put on the filter ready for use. At the end of the march the apparatus is set up in a few minutes; the cans or camp kettles are used to measure the water, to which a sufficient quantity of the powder is added by means of the small measure furnished with each container. After stirring, the water is poured into the filter can and the filter is then started. Within ten minutes after halting filtered water may be delivered to the troops. A larger apparatus is more elaborate, being furnished with a pump and means of automatically supplying the solutions of alum and soda to the water. This model with all its accessories crated for transport weighs about 390 pounds. Its capacity is 400 gallons per hour. As regards efficiency it may be said that in a series of experiments conducted by a board of officers of the army it was found that this filter removes about ninety-nine per cent. of the contained bacteria. Since the filter-cloths are sterilized daily by boiling, bacteria cannot multiply in them. The filter also removes all organic coloring matter, and all mud and clay, leaving the water clear and palatable.

#### Proceedings of Societies.

#### MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Annual Meeting, Held January 20, 1908.

The President, Dr. T. E. SATTERTHWAIT, in the Chair.

**Election of Officers.**—The following officers were elected: President, Dr. Robert T. Morris; corresponding and statistical secretary, Dr. Frank C. Raynor; treasurer, Dr. H. Ernest Gallant; chairman for the borough of Brooklyn, Dr. J. Scott Wood.

**Report of the Corresponding and Statistical Secretary.**—This report showed that during the year thirty-one new members had been elected, and that the total membership of the association was now 647.

**Ureteral Catheterism.**—In this paper Dr. F. TILDEN BROWN expressed his gratification at the increasing appreciation shown by the profession at large for the accurate diagnosis of urinary disorders and abnormalities of the urinary tract, which was only afforded by this differentiating practice. He then proceeded to give a demonstration of his combined cystoscopic and radiographic caddy, as well as one connected with the development of the cystoscope since Nitze and Leiter first made their wonderfully advanced presentation in 1870. The speaker said that since 1894, when after a successful and comparatively easy application of the unappreciated Brenner catheterism cystoscope in a

case of urinary tract tuberculosis (where the result served to decide an all important question as to surgical interference), he had been interested in testing the relative merits of the different catheterizing instruments existing at that period; and he was satisfied that for this purpose, in general, the direct vision cystoscope was possessed of more advantages and fewer disadvantages than the prismatic, or indirect, type. Hence his adoption of the Brenner pattern for his first efforts in development of the cystoscope. Dr. Brown's remarks were directed more particularly to instruments and methods with which he had himself had to do, and were supplemented by wall drawings and photographs to demonstrate the various developmental forms, since 1900, of his original "composite cystoscope," the identical instrument which a St. Louis cystoscopist had recently appropriated, and had been presenting as his own "universal cystoscope." This composite cystoscope, made by the Wappler Company, of New York, was a vastly more useful instrument than its immediate predecessor, the author's double catheter direct vision cystoscope, which Leiter, of Vienna, made for him in 1898, and which was the first telescopic cystoscope, of any form, to provide for two catheters and effect synchronous catheterism of the ureters. But this Vienna instrument had no reserve channels for irrigation. It was with the end in view of finding a way to add such irrigation channels to the already practicable double catheter direct vision cystoscope, while, at the same time, not increasing the circumference of the shaft beyond 24 French, that the Brown-Wappler efforts were first directed, in 1900. With what initial success these efforts had met and what constantly added improvements he expected, the present presentation was intended to fully demonstrate. It should be here added that the speaker's first double catheter instrument was but a modification of the then existing Brenner single cystoscope, whereas his subsequent instruments involved a wholly novel departure from all the preexisting types. The first essential change lay in getting rid of the old time terminal window at the vesical end of the sheath, and this was followed by the use of different kinds of interchangeable telescopic tubes for the same common sheath. Up to the present time its development on this basis had resulted in giving us at least three complete cystoscopes for different purposes, adjustable in one sheath. Still another tube, of paramount value, to go with this common sheath, was all but completed, in the shape of an indirect vision double catheter telescope, which would be welcome to those who preferred this method of ureter catheterism to the direct one, and which here in America had been gaining constantly in favor since the first introduction of the composite cystoscope.

As to the uses of ureteral catheterism, Dr. Brown said these might come under two heads—diagnostic and therapeutic. The latter, in his belief, were quite limited, and it was also his opinion that those enthusiasts over kidney lavage of a few years ago who, missing the diagnostic resources of this procedure, professed to meet with so vast a number of patients with pyelitis as to astonish others who had long been studying such conditions with intel-

ligence, and by the aid of this same differentiating means—not only had they discovered that pyelitis was very common, but, furthermore, that it was a leading factor in the causation of Bright's disease. From such original deductions, regarding both the prevalence of pyelitis and their new aetiology of Bright's disease, it was not difficult to foresee what a marked change the future mortality statistics, in connection with such forms of renal disease, when treated by their medicated lavage of the pelvis, would show! The speaker said that he could appreciate the fact that there were exceptional cases of pyelitis which would be advantageously treated, at least in part, by this method, but that for the great majority internal medication, together with climate, hygiene, and diet, would be much more efficient and vastly safer.

The therapeutic use of the ureter catheter, on the other hand, in cases of stones lodged in the ureter was, from the speaker's experience, one of considerable importance. In not a few the descent of such calculi had been determined at once or in intermittent stages, by the stretching incidental to the introduction of the catheter. Besides this mechanical effect of the catheter it was of undoubted service in such cases, when the eye of the catheter had reached a point above the lodged calculus, either to use warm gomanol oil or add to the existing urinary hydrostatic pressure by the guarded and gradual injection of warm boric or saline solution. The efficacy of the ureter catheter for the immediate relief of some cases of acute hydronephrosis by carefully insinuating the eye of the catheter past the mechanical barrier (whether this was stricture of the ureter, angling of the ureter, or impaction of a calculus) was self evident. Where, in such cases, the catheter was successfully used, it was at once appreciated as being a therapeutic and diagnostic resource of the greatest value.

The last therapeutic purpose of the ureter catheter referred to by the speaker was that of serving as a tubular splint for a partly or completely severed ureter, whether such was the result of accident in abdominopelvic surgery or of any compression trauma of this tube incidental to accidents. Not only would extravasation be prevented by draining the urine past such laceration, but the presence of the catheter also served as a mandrel during the suture of the ureter.

The second, or diagnostic, class of uses of the ureteral catheter was altogether too numerous and too well recognized to require comment, even if time permitted. Upon only one, as yet not well appreciated, field of value the speaker said he would dwell for a moment. This was the combined use of radiography with ureter catheterism. It was a well known fact that many plates of the bony pelvis revealed shadows which, as regarded shape and position, it was impossible for even the most expert interpreters of x ray plates to say whether they represented a calculus in the ureter or some simulating body in the immediate vicinity. When these shadows were found in patients giving a fairly typical clinical history of lodged ureteral stone, the only nearly absolute safeguard for the surgeon, as well as the patient, against an unnecessary operation was to be had from this practice of first

passing a ureteral catheter to a distance beyond the site of this previously recognized questionable shadow, then inserting a metal stylet (preferably of platinum) into the catheter, and again making an x ray picture of both. Of course when the questionable former shadow was seen to be in the same anteroposterior plane as the shadow of the metal stylet—in other words, when these were apparently in direct contact—the diagnosis was materially strengthened. On the other hand, if an appreciable space existed between the two shadows, the diagnosis was almost negated. A double ureter or encysted calculus would need to be involved if the diagnosis was still to be maintained. The speaker showed photographic prints from x ray plates illustrative of all these conditions. It was because of the great value of this diagnostic resource that Dr. Brown had had made a table where this entire procedure could not only be carried out in the specialist's office, but where no essential change or movement of the patient's body was necessary after insertion of the stiletted catheter. In conclusion, he said that this and closely allied branches of x ray work were so essentially within the province of the genitourinary specialist that an office could not be said to be complete in its appointments without them.

**On the Newer Methods of Examining the Bladder.**—This paper was read by Dr. FREDERIC BIERHOFF (see *Journal*, pp. 588, *et seq.*).

**Notes on Overtreatment of the Urethra and Bladder.**—In this paper Dr. JAMES PEDERSEN presented reports of several cases which illustrated the bad effects of injudicious management. In one of these the patient, a young man of twenty-two, reported a slight urethral discharge to his physician, who told him there was no infection, and proceeded to pass a full sized sound. This gave him pain and caused some hæmorrhage, and on the following day he had a chill, followed by fever. There then developed an increasing frequency of urination, with progressive obstruction, and on the twentieth day after the passage of the sound complete retention occurred. It was then that Dr. Pedersen first saw the patient. With a rubber catheter, which was passed without difficulty, twenty-four ounces of chocolate colored urine was drawn from the over-distended bladder, and catheterism was repeated every eight hours. In two days fluctuation in the prostate made its appearance. The pus present was evacuated through a median vertical perineal incision, and at the end of eight days systematic treatment of the urethrocystitis and dilatation of the stricture were instituted.

In another case the patient, twenty-five years of age, had frequency of urination about five months after the disappearance of a urethritis lasting six months. About a month later he noticed a redness about the meatus, and shortly afterward there appeared a urethral discharge, which gradually increased. In a week's time it became greenish yellow in color, and by the end of another week he was suffering from very frequent and painful erections. Under the use of daily irrigations of the penile urethra by his family physician the discharge was reduced in six or seven days to an occasional morning drop, but although the irrigations were kept up regularly

for two months the one drop still continued. During this time, however, no attention was paid to the patient's adverse mode of life, the correction of which would no doubt have greatly aided recovery. The physician then gave an instillation of a ten per cent. solution of silver nitrate, and the consequences were disastrous. This patient was seen in consultation four days later by Dr. Pedersen, and the discharge, which promised to continue indefinitely, was then thin and purulent.

Another case was that of an unmarried man of thirty who had suffered much from ungratified sexual excitement, and one year previously had had a short attack of urethritis. This case, the speaker said, afforded a striking example of a total disregard of the patient's general condition and lack of recuperative power, for the man was anæmic and poorly nourished, and had undergone two operations (eight years apart) for osteomyelitis. Three months ago he began to suffer from pain and tenderness in some of his joints and bones, a scanty urethral discharge, frequent desire to urinate, loss of appetite, and general ill health. After three weeks' treatment by intravesical irrigation, sounds were passed every third day, as it was discovered that he had a stricture. The patient then went south for three weeks, and came back greatly improved in every respect. Dilatation was now resumed and practised more frequently than before, and the result was a return of the frequency and urgency of urination. The point which Dr. Pedersen said he wished to make was that, allowing for errors of judgment and in diagnosis, and for accidents from the use of instruments, there remained a fair number of cases of faulty treatment (chiefly overtreatment), in which a correct, or nearly correct, diagnosis had been made, but in which overzeal or overconfidence had led the physician into doing the patient an unwitting injustice.

**Conservative Prostatectomy.**—Dr. FOLLEN CABOT read this paper (see *Journal*, pp. 384, *et seq.*).

Dr. PARKER SYMS said that Dr. Brown was certainly to be congratulated on the admirable work which he had done. By his ingenious apparatus and technique he had added no little to the resources of surgery. He conceded freely that ureteral catheterism had a legitimate field, but this was a somewhat limited one. In hands as skilful and careful as those of Dr. Brown the procedure was an entirely safe one, but it seemed to him that the time had come when a note of warning should be given against its too promiscuous use. It should be limited, he thought, to cases in which other measures had failed and in which it was imperatively demanded for diagnostic purposes. With it there was danger of infecting the ureter, and if, from this, one kidney became infected, it might lead to disease of the other also. When infection was already present in the urinary tract, he thought ureteral catheterism should be avoided. Under any circumstances this procedure should be practised only by those specially skilled in its performance.

In speaking on Dr. Bierhoff's paper he said that the cystoscope was unquestionably of very great value. But, while this, too, had its dangers and limitations, and while the positive proof which it afforded was indisputable its negative proof was

not conclusive. Because the cystoscope did not reveal a certain condition in the bladder, it did not follow that that condition was not present. Taken all together, the evidence which this instrument afforded was not so exact as he wished that it was.

In regard to prostatectomy, we had now gone so far that surgeons were pretty generally agreed as to the propriety and indications of the operation, though differing more or less as to methods. Personally, he preferred the perineal route. He believed that the mortality was less with this than with the suprapubic—not the immediate mortality alone, but also that during the period of convalescence. One great advantage of the perineal operation was the short duration of confinement required. As a rule, he allowed his patients to get out of bed at the end of forty-eight hours, or certainly within three days. Suprapubic prostatectomy not only necessitated a longer confinement, but involved more danger in the subsequent convalescence. He was glad to learn that by conservative prostatectomy Dr. Cabot meant an operation in two stages. In selected cases he himself had followed this plan for the past ten years, and at times he had found it very useful. He recalled one case particularly in which the patient was almost moribund, and where he believed that to complete the operation at one sitting would certainly have proved fatal. Here he first drained the bladder, and later, after the patient had become much stronger through the relief thus afforded, he removed the prostate through the same incision. In all cases where a slightly increased loss of blood or a slightly longer anæsthesia would in all probability turn the tide against recovery, he now made it a practice to adopt the two operation plan.

Dr. G. MORGAN MUREN, of Brooklyn, said he agreed with Dr. Syms that at present the cystoscope was resorted to too often, and he believed that other useful means of diagnosis had been neglected by those who were enthusiastic cystoscopists. The patient's welfare was thus jeopardized by the too frequent resort to this instrument, although it was, in its legitimate place, one of great practical value. As regarded prostatectomy, he said that frequent reference had been made to selected cases, but no one had spoken about the unselected cases, those of old men whose general condition was such that any radical operation was likely to prove fatal. He had seen such patients die after suprapubic and after perineal prostatectomy, as well as after the two stage operation described by Dr. Cabot. In this class of cases Dr. Muren preferred the method of permanent suprapubic drainage of the bladder, which he said he had employed in a number of instances, making the incision required for the purpose under local anæsthesia. It was here most important to prevent the leakage of urine, and for this purpose he exhibited an apparatus with a plug attachment which he had devised and which he had found very serviceable.

Dr. MARTIN W. WARE said that the papers presented this evening had made it clear that, after all, the cystoscope was an instrument of precision. We should look upon it, he thought, in the same light as the microscope, on the findings of which we seldom relied solely, to the exclusion of other factors. Although the cystoscope was an instrument of precision, however, its proper use required a good deal

more care than was generally supposed to be the case. Its employment was never a procedure of exigency. After paying a tribute to the achievements of Dr. Brown in the field of ureteral cystoscopy, and extolling the value of his instruments, the speaker said that certain cases were met with in which the conditions were such that direct illumination of the ureteral orifices was impossible, and in which it was therefore necessary to resort to the Nitze cystoscope. While the possibility of infecting a healthy kidney by ureteral catheterism should be borne in mind, the danger of infection from this source, and particularly in tuberculous conditions, had no doubt been exaggerated. The proof was still entirely lacking that through this agency the opposite kidney had become infected, and he believed that any such contention was largely a myth. Cystoscopy in children constituted a field which was as yet not thoroughly opened up. In those under five years of age the calibre of the urethra was so small that the instruments thus far devised for the purpose of exploring the bladder had not proved satisfactory, on account of the small size of the prism which had to be used. He thought it might be of interest to know that the salpingoscope, an instrument which rhinologists used for exploring the orifices of the Eustachian tubes, had been employed with success by some operators in the case of young children. It was of the Nitze type, and the principal objection to it was the shortness of the shaft. This was one, however, which could be readily obviated.

Dr. BROWN said that, while he believed that in the vast majority of cases requiring ureteral catheterism the direct instrument could be used, and while he believed that method preferable for a variety of reasons (among them being the saving of time and the diminished risk of hæmorrhage), he fully appreciated the value of the indirect instrument in atypical cases. As to the supposed dangers attending ureteral catheterism, Dr. Ware had very well answered some of the criticisms made, and personally he was not aware of any accident having occurred in the cases he had examined. He had refused to take up this procedure, or even simple cystoscopy, until he had become convinced that it was possible to have all the apparatus employed completely sterilized. It would not do to resort to boiling for this purpose, but by repeated experiments he had proved that the vapor of formaldehyde was thoroughly efficient. He therefore did not think that his tools were dangerous, and, as he was equally careful to have the urethra and bladder properly cleansed, and to perform the operation under strict aseptic precautions generally, he believed the danger of infection was minimized. Even if the tip of a catheter which had become accidentally infected was introduced into a healthy ureter, he doubted whether the kidney would become involved, for it was now recognized that an ascending infection was apt to become less and less potent as it advanced. It was descending infection of the kidney which we had most to dread. There was a good deal of injury involved in the turning about of a searcher in cases of stone in the bladder; yet there was very little danger of infection from this source.

Dr. BERNHOFF said that his own preference was

for the indirect vision cystoscope, and he had been perfectly satisfied with the results obtained with this. He could not agree at all with Dr. Muren. If an examination was to be made, he did not think it was fair to the patient to experiment with an insufficient method. It was the duty of the surgeon to resort at once to the scientific procedure, cystoscopy. This, in the speaker's opinion, offered the maximum of information with the minimum of risk. The cystoscope was certainly not a safe instrument in the hands of an incompetent operator, but he had never seen a case in which complete asepsis was observed, and burning of the bladder wall avoided, which was followed by a reaction. In order to determine the existing condition, it was sometimes necessary, to have two sittings, or even more. He said that negative evidence did show something, and cited an illustrative case in which the diagnosis of hematuria of renal origin was made out. In reply to Dr. Ware, he said that it was not necessary to resort to the salpingoscope in the case of young children, for at present there were to be had special children's cystoscopes, which were longer than the salpingoscope and which, notwithstanding their small calibre, were perfectly satisfactory as regarded the results afforded.

Dr. PEDERSEN said that from his own experience he could confirm Dr. Brown's statement that calculi were sometimes more quickly got rid of after the passage of the ureteral catheter. He had also seen a stone lodged at the orifice of the ureter disengaged by the passage over it of the searcher. Radiography with a stiletted catheter in the ureter for the diagnosis of ureteral calculus he thought a matter of great interest. In a case of Dr. Forbes Hawkes's the shadow supposed to represent the calculus was at some distance from the catheter, and it seemed probable to him that this was one of those instances of bifurcated ureter which were sometimes met with. Therefore there was some danger of being misled by the evidence afforded by the x ray. Cystoscopy he believed to be absolutely safe when performed with proper precautions and under proper conditions. As to prostatectomy, he was convinced of the usefulness of the two stage operation in certain cases, and he thought that he had saved a patient's life last spring by means of it. In reply to Dr. Syms, he would say that perineal drainage after the first step was not always safe.

#### MEDICAL SOCIETY OF THE STATE OF NEW YORK.

*One Hundred and Second Annual Meeting, held in Albany,  
January 27, 28, 29, and 30, 1908.*

The President, Dr. FREDERIC C. CURTIS, of Albany, in the Chair.

(Continued from page 570.)

Dr. MORGAN, of New York, stated that the subject was too large to be properly discussed at that time, and that if he were called upon to give advice to beginners in the profession he would say, "Keep out of debt and remember that all cases of stomach and bowel trouble are not cases of stomach and bowel trouble."

He considered such names as hyperchlorhydria as high sounding but useless as to the expression of a pathological entity, and thought its only value lay in the impression the high sounding title made upon the patient, so that the doctor's directions would be more faithfully carried out. In nervous disease of the stomach he deemed it necessary to eliminate eye strain and the normal involution of the appendix.

Dr. DUNNING, of Orange County, asked for a reasonable explanation of the development of duodenal ulcer after extensive burns, also for a satisfactory method of diagnosing cancer in its early stages. She asked if the injection of trypsin in people not affected with malignancy would never give the tryptoglycogenic reaction, and if it was always present in patients so affected.

Dr. JACOBI believed that neuroses of the stomach usually meant nervous exhaustion. The diagnosis, he thought, between hyperchlorhydria, ulcer, and disease of the colon could be reached by the fact that in hyperchlorhydria the pain was often relieved by the taking of food. In ulcer it was increased soon after or even while eating, and in disease of the colon it came on two or three hours after the food had been taken. He never admitted so many articles of diet as Dr. Rochester had allowed, but his programme was "milk, milk, milk, with rarely a little stale bread." A small quantity of rice was also allowed at intervals, and bismuth and magnesia were administered. A cure might be hoped for in five or six weeks, and while this treatment was being carried on the patient would often take on flesh.

Dr. BULKLEY cited the case of a woman who ate her breakfast as usual, though she was to have an operation that day, but she did not eat any lunch. In the afternoon, when she was anesthetized, she vomited up the breakfast unchanged. He concluded from that that it was the nervous condition of the patient which retarded the digestion, and that nervous conditions from any other cause might also have the same effect.

Dr. COLLINS, of New York, believed the involved classification of gastric neuroses upon a thoroughly theoretical and hypothetical basis to be highly undesirable and to denote a retrogression of about fifty years. He defended the term hypochlorhydria as legitimate and signifying something.

Dr. ANGELL, of Rochester, wished to back up Dr. Collins in every particular. He considered the discussion of gastric neuroses as highly speculative.

Dr. WAYNE stated that in his experience, especially in the early stages of ulcer, the administration of food did not increase, but, on the contrary, relieved the pain.

Dr. MAYO wished to express his gratitude to Dr. Stockton for his excellent discussion. He stated that he always liked to discuss a question with Dr. Stockton because he believed that he as a surgeon might overestimate the surgical importance of conditions and not give the medical side of the question its proper consideration. While eighty-one per cent. of the cases of pancreatitis had been associated with gallstones, he hoped that the discussion would stimulate the medical department of the profession to investigate the cause of pancreatitis when no gallstone disease coexisted.

Dr. OCHSNER believed all cases of ulcer, when

they cannot be cured by a reasonable trial medically, to be surgical. He stated that when these cases did come to operation secondary changes, such as pyloric obstruction, dilatation, or adhesions to other organs, had occurred. The cause of ulcer of the duodenum following burns was purely theoretical, as was also the trypsin diagnosis of cancer, though he was very glad to have had it brought up.

(To be continued.)

## Letters to the Editors.

### A CATECHISM FOR PHYSICIANS.

LANARK, ONT., March 31, 1908.

#### To the Editors:

As an old subscriber and ardent admirer of your journal, allow me to make a suggestion pertaining to the personal side of our fraternity, in the shape of questions which thousands of the subscribers would willingly answer. The answers could be tabulated according to their frequency and importance.

1. Is it your ambition to earn enough in a certain time limit to be able to live at ease without practising the profession?
2. Are you desirous of municipal or political honors plus what they may bring in a financial way?
3. Would a good property (your business location) and a good life insurance, in keeping with your income, satisfy your money ambitions?
4. Do your poor patients get as good attention as you well to do ones?
5. Do you read medical works and magazines, besides other up to date literature, daily?
6. Do you strive to keep in touch with and on friendly terms with your professional neighbors?
7. Do you belong to the local medical association or any other?
8. What are your intellectual and physical hobbies (if any)?
9. Are you of a mechanical nature as regards the use of your hands and head?
10. Are you prepared and capable to attack ninety per cent. of surgical difficulties?
11. What is your present ambition?

J. E. KLOTZ.

## Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

*Essentials of Modern Electrotherapeutics.* An Elementary Textbook on the Scientific Therapeutic Use of Electricity and Radiant Energy. By FREDERICK FINCH STRONG, M. D., Instructor in Electrotherapeutics at Tufts College Medical School, Boston. New York: Rebman Company, 1908. Pp. x-112.

This little book contains in a very handy form the elements of the scientific therapeutic use of electricity and radiant energy. The author does not presuppose much elementary knowledge in his reader, and introduces him immediately *in medias res*. He speaks of the modern theories of matter, force, and the fundamental laws and principles of electrophysics (Chapters I and II). After physi-

ology has been considered from the electrical standpoint in Chapter III, galvanism and faradism are treated in Chapters IV and V. Electrodiagnosis is the subject of Chapter VI, while in Chapters VII, VIII, and IX are mentioned the types of static machines, high frequency currents, and Röntgen rays. Phototherapy is spoken of in Chapter X, and the therapeutic use of ozone in Chapter XI.

The illustrations which accompany the text are well executed and will be of great help in understanding the subject. The book will be welcomed by every practitioner who is not an expert or specialist in this branch of medicine, and by every student.

*A Textbook of Surgical Anatomy.* By WILLIAM FRANCIS CAMPBELL, M. D., Professor of Anatomy, Long Island College Hospital, etc. With 319 Original Illustrations. Philadelphia and London: W. B. Saunders Company, 1908. Pp. 675.

Scattered through the pages of this book there is indeed a good deal of what may properly be called surgical anatomy, but essentially it deals with descriptive anatomy from the regional point of view. The author speaks of it as an "applied anatomy," and in so doing he appears to us to be correct, for he makes his anatomical teaching apply quite largely to medical as well as to surgical practice. On this account the book will prove of value to practitioners in general. The pictorial illustrations are numerous and clear. In one respect some of them are strikingly different from the lugubrious pictures of the older anatomical works; where the face is shown, it is usually a living and cheerful face, not that of a corpse. This is particularly true of Fig. 89 (page 174), which depicts a young woman from whom a generous slice of flesh has been removed so as to show the proximal ends of the subclavian vessels, which have been cut through. In spite of this mutilation, the girl's face shows no sign of distress.

*The History of the Study of Medicine in the British Isles.* The Fitz-Patrick Lectures for 1905-6. Delivered before the Royal College of Physicians of London. By NORMAN MOORE, M. D. Cantab., Fellow of the Royal College of Physicians, etc. Oxford: The Clarendon Press, 1908. Pp. vi-202.

This book consists of four lectures. In the first of these lectures the author, after a short introduction in which he also mentions Dr. Thomas Fitz-Patrick, in whose honor the Fitz-Patrick lectures were founded by Mrs. Fitz-Patrick, speaks of medical study in London during the Middle Ages, exemplifying it with the description of the life of John Mirfield, who lived in London and died about 1258. He also mentions among others a medicus Grimbaldus, who witnessed in 1105 the signatures to a grant. A copy of this document faces the title page, while the text itself will be found in the appendix.

The second lecture treats of the education of physicians in London in the seventeenth century. Here are described the lives of Nicholas, of Casa, Dr. Thomas Linacre, the founder and first president of the College of Physicians (founded in 1518), and others. But the representative of this period is Dr. Edward Browne, who died in 1708.

The third and fourth lectures give the history of the study of clinical medicine in the British Islands. The first part is given over to Sir Theodore Turquet Mayerne (died in 1655), who reported on the death of King James I and Queen Henrietta Maria.

These documents are well translated in the text, and the Latin originals are to be found in the appendix. Several letters from the royal personages to their body physician are given. Sir Theodore was also a friend of William Harvey. Mayerne's, Harvey's, Glisson's, Sydenham's, and others' influence upon the study of medicine in England is mentioned, and Boerhaave's upon Scotland and Ireland. The appendix contains also a note of Harvey on Galen. A very complete index is of great advantage.

The book has been marvelously compiled and arranged; the labor and researches of Dr. Norman Moore must be greatly admired; and the Royal College of Physicians is to be congratulated on having entrusted the Fitz-Patrick lectures to such a scholar. We can recommend the book to every physician as a recreation after the duties of a strenuous day.

*Jahresbericht über die Leistungen und Fortschritte auf dem Gebiete der Erkrankungen des Urogenitalapparates.* Begründet von Prof. Dr. M. NITZE und Dr. S. JACOBY, Berlin. Herausgegeben von Priv. Doz. Dr. ALBU, Berlin; Prof. Dr. R. DU BOIS-REYMOND, Berlin, etc. Und unter Mitwirkung von J. ALBARRAN, Paris; A. BIER, Berlin; H. FENWICK, London; A. VON FRISCH, Wien; H. KUMMELL, Hamburg; H. Young, Baltimore. Redigiert von Prof. Dr. A. KOLLMANN, Leipzig, und Dr. S. JACOBY, in Berlin. II. Jahrgang, Bericht über das Jahr 1906. Berlin: S. Karger, 1907. Pp. 452.

This second volume of the yearbook of urology represents the advances made in this branch during the year 1906. It does not differ materially from the first volume, issued for 1905, which we reviewed here last year. The death of Professor Nitzte in 1906 necessitated a change in the editorial management, and Professor Kollmann, of Leipsic, took up the work of the distinguished cystoscopist. Dr. Hugh Young, of Baltimore, and Dr. Krotoszyner, of San Francisco, represent this country on the editorial staff of the yearbook. In this volume there is a slightly diminished tendency to quote principally German authorities and authors, so that the yearbook is gradually assuming a more international character. It presents a very fair collection of abstracts on every subject pertaining to urology, and will prove very useful to compilers of literature and to writers and students who follow the progress of urology from year to year.

*Clinical Therapeutics.* A Handbook on the Special Treatment of Internal Disease. By ALFRED C. CROFTAN, Author of *Clinical Urology*. Second Edition, Revised. Chicago: Cleveland Press, 1907. Pp. 626.

The first edition of Dr. Croftan's very useful book has been rapidly exhausted, and within a few months this second issue has been launched. There have been no great advances in therapeutics within that short space of time, but the book has undergone careful revision. It represents undoubtedly not only one of the most practical, but also one of the most readable and convenient works on the treatment of disease that have appeared within recent years. There is nothing in the book that suggests the old textbooks on materia medica and therapeutics. It is purely a clinical work, dealing with diseases, symptoms, and complications as they occur in every day work and giving precise directions, with the reasons therefor, for treatment. Numerous useful prescriptions appear in the text,

but the author has made it a point to include all the modern methods of physical and dietetic treatment. Accurate, detailed directions are given for the carrying out of these methods, so that with this book alone on hand a practitioner can follow out the treatment of disease in all its phases. We strongly recommend the book, being convinced of its value, and satisfied by practical experience with it, that it will prove acceptable to practitioners.

*The Operative Treatment of Prolapse and Retroversion of the Uterus.* By J. INGLIS PARSONS, M. D., M. R. C. P., M. R. C. S., Physician to the Chelsea Hospital for Women; Late Surgeon to the Royal Maternity Charity Hospital; Fellow of the Royal Medical and Chirurgical Society, etc. London: John Bale, Sons, and Danielsson, Ltd. Pp. viii-90.

The purpose of this little monograph is to exploit the author's operation for prolapse of the uterus. Briefly, this consists in the injection into each broad ligament of a solution of quinine, which, producing an effusion, brings about the deposit of fibrous connective tissue, and that, in turn, gives firm support to the uterus. The author alleges, among the advantages of this procedure, painlessness and absence of shock and hemorrhage. His own experiences in 105 cases have been entirely satisfactory to him. The uterus expands easily during pregnancy, and is not placed in abnormal positions. The technics of the operation are fully described and illustrated.

*Diseases of the Male Generative Organs.* By EDRED M. CORNER, M. A., M. B., B. Sc., F. R. C. S., Surgeon to Out-Patients, St. Thomas's Hospital, etc. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1907. Pp. x-279.

This little manual forms a part of a series of monographs. It deals with diseases of the generative, as distinct from the urinary organs, and therefore includes a brief description of the diseases of the testicle and its envelopes, of the epididymis, the spermatic cord, and the seminal vesicles. Some of the diseases of the penis, prepuce, and scrotum bearing upon the generative function have been included. The diseases of the prostate are considered in another volume of the series. It is a rather odd notion, to deal with diseases of the genitourinary organs in their relations solely to the generative function. We do not, for our part, see the special need of dealing with strictures of the urethra, for instance, from the point of view of their influence upon the sexual function. However, the book is one which it is a pleasure to read, and it will prove very useful to students taking special courses in this particular line of work. It is compact and convenient to carry in its flexible cover. Its contents represent rather informal talks in the style of a clinical lecture than formal essays.

*Essentials of Obstetrics.* By CHARLES JEWETT, A. M., M. D., Sc. D., Professor of Obstetrics and Gynecology in the Long Island College Hospital and Obstetrician and Gynecologist to the Hospital, etc. Assisted by HAROLD F. JEWETT, M. D. Third Edition, Revised and Enlarged. Illustrated by Thirty Illustrations and Five Colored Plates. Philadelphia: Lea Brothers & Co., 1907. Pp. vi+17 to 413.

The popular success of Dr. Jewett's little book is made evident by the appearance of the third edition. As an introduction to more extensive works and as

a guide to lectures, it fulfils its purpose admirably by bringing before the student the essential facts of the subject. While the illustrations are mainly schematic, they are well adapted to their didactic purpose.

*The Medical and Surgical Uses of Electricity, Including the X Ray, Phototherapy, the Finzen Light, Vibratory Therapeutics, High Frequency Currents, and Radioactivity.* By A. D. ROCKWELL, A. M., M. D., Neurologist and Electrotherapist to the Flushing Hospital, etc. With Two Hundred and Fifty-nine Illustrations. New York: E. B. Treat & Co., 1907. Pp. xvi-676.

The present edition, which is practically the eleventh of Beard and Rockwell's standard work, has been thoroughly revised. Many chapters have been rewritten and much new material has been added. Especially is this the case in the chapters on high frequency currents, on x ray diagnosis and therapeutics, on phototherapy, and on radioactivity.

It has been the aim of the author to present in book form the results of his own labors and of the researches of all other investigators in electrotherapeutics. He has well succeeded, and the summary thus obtained, which he places before his readers, is practical and exhaustive, and the book can well be recommended.

*Lehrbuch der spezifischen Diagnostik und Therapie der Tuberkulose.* Für Ärzte und Studierende. Von Dr. BANDELIER, dirigierendem Arzte der Lungenheilstätte Cottbus, und Dr. ROEPKE, dirigierendem Arzte der Eisenbahnheilstätte Melsungen. Mit 18 Temperaturkurven, auf 5 lithographischen Tafeln. Würzburg: A. Stuber, 1908. Pp. 113.

Bandelier and Roepke have collected data from their experience, and have thus written a book from practice for practice. The book is divided into three parts: The specific diagnosis of tuberculosis, the treatment of tuberculosis of the lungs, and the treatment of tuberculosis of other organs. A general introduction precedes the main body of the work, and a conclusion follows it. The bibliography comprises seventy-three reference books and articles, of which number three are French, one is English, and one is Italian, the rest are German and Austrian.

The authors wish to call the attention of the profession to the use of tuberculin. They speak of old tuberculin, new tuberculin, and new tuberculin bacilli emulsion; Denys's tuberculin; Klebs's tuberculin; Beranek's tuberculin; Spengler's bovine tuberculosis tuberculin therapy; von Behring's specific remedy; other tuberculins following Koch's method; the immunization methods following Jenner and Pasteur's theories; and nastin. These they classify as active immunizing remedies, while the passive ones are Maragliano's serum; Figari's hæmoantitoxine; Marmorek's antituberculosis serum, and streptococci sera. The book contains also very interesting statistical material.

#### BOOKS, PAMPHLETS, ETC., RECEIVED.

*Medical Gynecology.* By Howard A. Kelly, A. B., LL. D., F. R. C. S. (Hon. Edinb.), Professor of Gynecological Surgery in the Johns Hopkins University, Gynecologist to the Johns Hopkins Hospital, Baltimore, etc. With One Hundred and Sixty-three Illustrations, for the Most Part by Max Broedel and A. Horn. New York and London: D. Appleton & Co., 1908. Pp. 662.

Transactions of the American Climatological Association. For the Year 1907. Volume XXIII. Pp. 330.

## Miscellany.

**George Sand and Her Lovers.**—An interesting problem in literary clinics is discussed in Mr. Francis Gribble's new book, *George Sand and Her Lovers*. What was the nature of the illness through which the novelist nursed Alfred de Musset when she was living with him at Venice? Dr. Pagello, who, while attending the patient, supplanted him in the affections of his mistress, writes: "I diagnosed a nervous typhoid fever." That, of course, is nonsense. Nervous typhoid fever is a complication unknown to medicine, and typhoid fever itself was unknown to medicine in the year 1834. Typhoid and typhus were at that date confounded and called "continued fever." It follows that the alleged diagnosis was really an afterthought; and the record of the symptoms indicates that the afterthought was due, not to increased pathological knowledge, but to a desire to protect the poet's reputation by tampering with the truth. "When," as Mr. Gribble writes, "we find the delirious patient seeing 'phantoms' round his bed, needing to be held down by two strong men, warned by his doctor during his convalescence to avoid strong drink, suspected of obtaining it surreptitiously, and relapsing, we know pretty well what to think." What we feel compelled to think is, of course, that the disorder from which Musset was suffering was delirium tremens. We feel as certain of that as it is possible to be of the malady of any patient whom we have not actually had under observation. The fact—a "new fact" in literary history—may perhaps in some measure explain the facility with which George Sand transferred her affections from the sufferer to his medical attendant, though it certainly cannot be said that it makes Pagello's conduct in kissing her behind the screen, as Musset averred that he did, any the more excusable from the point of view either of morality or of professional etiquette.—From *The Practitioner*, March, 1908.

**Sugar in the Soldier's Ration.**—In the April number of the *Archives de médecine et de pharmacie militaires*, Major P. Joly presents the results of a series of experiments on sugar in the field ration of the foot soldier, in the 94th French Infantry Regiment during the autumn manoeuvres of 1906, from which he concludes that: 1. Two companies, respectively, of 142 and 149 men, without any previous selection, were able to absorb, during twenty or seventeen days, a daily dose of sugar varying from 60 to 165 grammes without any digestive trouble or other signs of intolerance resulting therefrom. 2. A hundred grammes of fresh meat may be replaced in the daily ration by a hundred grammes of sugar without the men perceiving the diminution in the amount of meat. They accepted readily, and most of them with great pleasure, the addition of sugar in the form of sweetened drink—coffee, wines, or water. 3. The substitution of 120 grammes of sugar for the hundred grammes of fresh meat resulted in improvement in the physiological condition of men subject to muscular exertion, decreasing the number of heart beats, the respiratory rhythm, and the weight of the body consecutively; augmenting the physical resistance and decreasing the sick rate. 4. The over-

**Public Health and Marine Hospital Service:**

*Official list of changes of stations and duties of commissioned and noncommissioned officers of the United States Public Health and Marine Hospital Service for the fourteen days ending April 1, 1908:*

AMESSE, J. W., Passed Assistant Surgeon. Relieved from temporary duty in the Hygienic Laboratory, Washington, D. C., and directed to rejoin his station at Havana, Cuba.

ANDERSON, J. F., Passed Assistant Surgeon. Directed to proceed to Asheville, N. C., for special temporary duty, upon completion of which to rejoin his station in the Hygienic Laboratory, Washington, D. C.

BRYAN, W. M., Assistant Surgeon. Temporarily relieved from duty at New Orleans, and directed to proceed to New Orleans Quarantine Station, reporting to the medical officer in command for duty.

CARMICHAEL, D. A., Surgeon. Granted leave of absence for ten days, from March 25, 1908, on account of sickness.

DE VALIN, HUGH, Assistant Surgeon. Relieved from duty at New Orleans Quarantine Station and directed to proceed to Savannah Quarantine Station and assume charge at that port.

GUSTEITER, A. L., Acting Assistant Surgeon. Granted leave of absence for four days, from March 3, 1908, on account of sickness.

FISTER, S. B., Acting Assistant Surgeon. Granted leave of absence for fifteen days, from April 6, 1908.

JACKSON, J. M., Jr., Acting Assistant Surgeon. Granted leave of absence for seven days from April 14, 1908.

KALLOCH, P. C., Surgeon. Directed to proceed to Bradford, Me., for special temporary duty, upon completion of which to rejoin his station at Portland.

KEATLEY, H. W., Acting Assistant Surgeon. Granted leave of absence for one day, March 10, 1908, under paragraph 210, Service Regulations.

SIMONSON, G. T., Acting Assistant Surgeon. Granted leave of absence for two days, from March 31, 1908.

TARBELL, B. C., Acting Assistant Surgeon. Granted leave of absence for thirty days, from April 1, 1908, and excused without pay for a further period of two weeks from expiration of leave.

WARREN, B. S., Passed Assistant Surgeon. Detailed to represent the service at the annual meeting of the Oklahoma State Medical Association at Sulphur, Okla., May 14-16, 1908.

WIGHTMAN, W. M., Assistant Surgeon. Granted leave of absence for seven days, from March 1, 1908.

*Board Convened.*

A board of medical officers was convened to meet at Boston, Mass., April 9, 1908, for the purpose of making physical examination of an officer of the Revenue Cutter Service. Detail for the board: Surgeon R. M. Woodward, chairman; Assistant Surgeon T. W. Salmon, recorder.

*Resignation.*

Resignation of Assistant Surgeon R. B. Scofield accepted, by direction of the President, to take effect April 17, 1908.

**Army Intelligence:**

*Official list of changes in the stations and duties of officers serving in the medical department of the United States Army for the week ending April 4, 1908:*

CLAYTON, J. B., Captain and Assistant Surgeon. Will report in person to Major William C. Borden, Surgeon, president of the examining board at Manila, P. I., at such time as may be required by the board for examination for promotion to the rank of major.

DEAN, E. A., Captain and Assistant Surgeon. Will report in person to Major William C. Borden, Surgeon, president of the examining board at Manila, P. I., at such time as may be required by the board for examination for promotion to the rank of major.

HARRIS, J. R., Captain and Assistant Surgeon. Relieved from further treatment at the General Hospital, Presidio of San Francisco, Cal., and ordered to return to station, Fort Worden, Washington.

HEINZMAN, C. L., Colonel and Assistant Surgeon General. Retired from active service, upon his own application, after forty years' service.

KIEFFER, C. F., Major and Surgeon. Retired from active service on account of disability, to take effect June 24, 1908, and granted leave of absence to include that date.

**Navy Intelligence:**

*Official list of changes in the medical corps of the United States Navy for the week ending April 4, 1908:*

BAKER, M. C., Assistant Surgeon. Detached from duty on the Midway Islands and ordered to the Navy Yard, Mare Island, Cal.

LEACH, P., Surgeon. Ordered home to await orders, when discharged from treatment at the Army and Navy Hospital, Hot Springs, Ark.

KOLTES, F. X., Assistant Surgeon. Detached from the Naval Medical School, Washington, D. C., and ordered to the Navy Yard, Mare Island, Cal.

PUCK, R. F. S., Pharmacist. Ordered to the naval training station, San Francisco, Cal.

**Births, Marriages, and Deaths.***Married.*

ANDERSON—HUNT.—In Birmingham, Alabama, on Saturday, March 21st, Dr. J. Henry Anderson and Miss Daisy Hunt.

DOLL—RUSSELL.—In St. Louis, Missouri, on Tuesday, March 24th, Dr. Joseph Doll and Dr. Libby Russell.

STEIN—BEDFORD.—In Scranton, Pennsylvania, on Thursday, March 26th, Dr. James Stein and Miss Sadie May Bedford.

*Died.*

BAILEY.—In San Francisco, California, on Tuesday, March 24th, Brigadier General Elisha I. Bailey, United States Army (retired), aged eighty-three years.

CANNADAY.—In Jacks Mills, Floyd County, Virginia, on Friday, March 20th, Dr. Asa H. Cannaday.

CARTER.—In Meridian, Mississippi, on Tuesday, March 24th, Dr. N. G. Carter.

CHANDLER.—In Cornwall, New York, on Saturday, March 21st, Dr. Daniel Henry Chandler.

CRUMP.—In Millersburg, Ohio, on Thursday, March 19th, Dr. A. A. Crump, Sr., aged eighty-eight years.

DWIGHT.—In Philadelphia, on Wednesday, April 1st, Dr. Henry E. Dwight, aged seventy-five years.

FASSETT.—In New York, on Tuesday, March 24th, Dr. Bryant Sloat Fassett, aged twenty-eight years.

GILLET.—In Detroit, Michigan, on Thursday, April 2d, Dr. Wilbur Gillet.

HEALY.—In New York, on Sunday, March 29th, Dr. James Redmond Healy, aged fifty-eight years.

JUDD.—In Philadelphia, on Wednesday, March 18th, Dr. Leonardo D. Judd, aged sixty-six years.

ORR.—In St. Louis, Missouri, on Saturday, March 28th, Dr. Charles J. Orr, aged forty-four years.

PENNINGTON.—In Brooklyn, N. Y., on Monday, March 30th, Dr. William J. Pennington, aged forty-one years.

ROBINSON.—In Boston, on Sunday, March 29th, Dr. Albert Brown Robinson, aged seventy-three years.

SPEAR.—In Norristown, Pennsylvania, on Friday, April 3d, Dr. John C. Spear, United States Navy (retired).

THIBODAUX.—In Napoleonville, Louisiana, on Sunday, March 22d, Dr. O. J. Thibodaux, aged forty-two years.

THOMSON.—In Belchertown, Massachusetts, on Sunday, March 29th, Dr. Edmund Sanford Thomson, aged forty years.

#### A COLONY SANATORIUM FOR THE NERVOUS AND NEURASTHENIC; A MUCH NEEDED WORK OF PHILANTHROPY.

BY GEORGE W. JACOBY, M. D.,  
New York.

Whether those statistics which show an increase in functional nervous diseases are correct or not, is a question which I should not care to discuss, but it is certain that we are constantly hearing and reading of the alarming manner in which neuroses and psychoses are augmenting, while nowhere can we find any statement that either the former or the latter are diminishing in frequency. Nor should we be astonished if such an increase were proved to be a fact, for the present day life makes constantly growing demands upon the nervous system of every individual; modern educational requirements, the ever extending competition in business and professional life, the rapid popularization of the use of new inventions, are all factors which put an additional stress upon a brain which has not as yet adapted itself to the conditions with which it has to cope.

If we admit the fact that there is such an increase, as it seems we must, then we cannot avoid asking whether the progress of these diseases, affections which constitute a menace to the welfare and happiness of many individuals and families, which destroy the economic worth of many people, which annually deprive the state of many of its best workers, cannot in some way be opposed.

Before answering this question, it will be necessary to review briefly some of the causes which produce these troubles, and to give thought to the conditions under which they occur.

In so doing, as well as in discussing their prophylaxis and contravention, much will necessarily be said which is elementary, and which has been said time and time again, but these things do not lose in weight through repetition and reiteration, and they cannot be said too often.

The confines of the various disorders called neurasthenia, hysteria, and nervousness interweave and overlap at many points, so that no sharp line of demarcation can be drawn between them.

Nevertheless, an effort should be made to distinguish between neurasthenia, which is always pathological, and the nervousness which may exist within physiological limits, at least, we need in a way specify what we mean by these expressions.

For the terms nervousness, nervous prostration, and neurasthenia are used by many physicians as expressive of one and the same condition.

Popular opinion here seems to draw a more distinct line, and we find our patients speaking of nervousness and neurasthenia with the understanding that the former is a more or less temporary condition, and that the latter is an actual disease. And we physicians must admit that this is correct; for, while neurasthenia is an affection which consists of a premature exhaustion and an untimely inhibition or arrest of function, occurring usually in a neuropath, frequently in a psychopath by birth, nervousness, on the other hand, is a condition which may be produced in anyone, even in the most robust.

The expectant attention caused by portending events, the effects of sickness with its physical and psychic drain, all produce a condition which we call nervousness and which passes away with its producing cause. In contradistinction to this transitory nervousness, there is still another form which is more or less permanent, frequently congenital, and found among all classes of people.

Persons so afflicted appear perfectly healthy, but are the possessors of a nervous system which reacts differently to external impressions from that of a normal person. Slight excitations produce unusually strong sensations; disordered equilibrium, pain, and emotions of an ultrapositive kind are produced by inadequate causes; this nervous person can exert himself, can, under pressure, do even more than circumstances require of him, and never is there a question of the occurrence of more than physiological fatigue.

Neurasthenia, on the other hand, is characterized mainly by an abnormal exhaustibility. The neurasthenic is at the end of his forces, he is unable to go on any longer, he is tired out; even under pressure he cannot force himself, and this exhaustibility implicates not only the somatic processes, but first and foremost the psychic ones. It would seem as though the entire exhaustibility was primarily of psychic origin.

Associated and going hand in hand with this exhaustibility there is always a more or less constant uniform excitability and irritability of all sensory apparatus, with the result that normal sensory impressions, as well as the physiological performance of the functions of internal organs, are abnormally perceived and create feelings of distress.

Just as no distinct line of demarcation can be drawn between nervousness, neurasthenia, hysteria, and other allied affections, so the causes of all of these affections may fittingly be discussed together.

Neither condition comes on suddenly, like lightning from a clear sky, but each requires time for its development. While neurasthenia frequently makes its appearance with an apparently sudden onset—and such a state has been called “acute neurasthenia”—the fact remains that such an acute onset is merely the culmination of a series of events, the climax in a tragedy. Even when this affection occurs in young children—and Oppenheim says that he has seen the severe form occurring in a child two and a half years old, and has treated many children between the ages of three and five years suffering from this trouble—it is always a result of accumulated previous causes.

Of such preceding causes, the most important is heredity. Precisely as in infectious diseases a certain soil is necessary for the growth of the virus, so here there is frequently inherited a predisposition which renders the individual less resistant to certain noxious influences to which everyone is more or less exposed.

While such a disposition may be an acquired one, in the vast majority of instances it is congenital, i. e., inherited, and due to the same troubles or to other nervous affections in the ancestors. The greater such predisposition, the more easily will the influences to which everyone is exposed exert their action in a causative way and bring about the troubles of which we speak.

First and foremost among the actually exciting ones are those which act psychically. Emotional excitations of all kinds, whether single and severe or repeated and mild, are the most potent. Thus we find that the struggle for existence among the conditions of modern life, especially among those found in the large centers of industrial and scientific activity, and the steady, persistent work with its attendant sorrows, deprivations, and over-anxiety for success, are among the most prolific causes; causes which are the results of conditions from which, for the large mass of people, there has been no possibility of escape.

Especially here in America are people forced into surroundings for which they have never been fitted, and especially here are premature demands made upon their nervous system before they are mature and properly qualified. This lack of proper training deprives many of the workers, in all branches, of the best protection against functional nervous diseases, which any person can have, namely, a well trained nervous system.

This struggle for existence by the congenital neuropath or the educationally unfit forces many to the use and then to the abuse of stimulants and excitants, and herein we have another important exciting cause.

This early and excessive use of coffee, tea, alcohol, and tobacco is especially deleterious in its action upon the nervous system of those very ones who are most prone to go to excess in their use.

Therefore, predisposition, aided by the storm and stress of active competition and abetted by the use of stimulants, must be looked upon as the main cause for the premature collapse of nerve force which we call neurasthenia; so it will be found that the majority of neurasthenics are between twenty-five and fifty years of age, and that their occupa-

tions are those which are attended by worry, undue excitement, uncertainty, excessive wear and tear, and thus we find mentally active persons more easily affected than those whose occupation is solely physical. Authors, actors, schoolteachers, governesses, telegraph and telephone operators are among those most frequently affected, and the increase of neurasthenia among women dates from the modern era which has opened to them new channels of work and has admitted them more generally into the so called learned professions. But whatever may be the occupation in which persons have broken down, it is never the occupation alone which has been the cause.

This cannot be too often repeated. The emotional fitness or unfitness of an individual for his occupation is of the utmost importance as a causative factor, and overwork alone, without any emotional cause and without any errors in mode of life, will never act to produce such a collapse.

It is, therefore, not astonishing that this class of functional nervous diseases is not confined to the wealthy, and that the rich and the poor are indiscriminately affected. But certain causes are of greater influence in the one class, while different ones obtain in the other. Poverty in itself, with its limitations of proper rest and recuperation, is a very positive cause. Years of neurological dispensary work among the poor have convinced me that nervousness, neurasthenia, hysteria, etc., are quite as prevalent among the indigent as among the well to do.

Other factors which are prominent in the production of neurasthenia are those which are caused by family environment, and which are intimately associated with the entire atmosphere of the home. Here the very causes which have made themselves felt in the sowing of the hereditary seed continue to exist and act as a fertilizer upon the very soil which they have helped to produce.

Each year the endeavor to attain satisfactory prophylactic measures in all fields of medicine becomes more and more pronounced. This very prophylaxis is the chief end of hygiene, and the enormous progress which this branch of bionomy has attained must merit the recognition and approbation of every worker in every branch of clinical medicine. We, who see a great deal of functional nervous disorders, cannot but express the hope that prophylactic measures, which have accomplished so much in the direction of infectious diseases and give promise of the ultimate eradication of typhoid fever and tuberculosis, may in some way also aid in preventing, or in counteracting, the spread of those affections which we are now considering.

When it is remembered that neurasthenia implicates the productive stage of life, and incapacitates, not only for days and weeks, as do so many epidemic diseases, but for months and years, and even for an entire lifetime; and when we also consider the social and material impoverishment of the individual and of his family caused by this and analogous affections—then we can appreciate how great a saving of suffering and deprivation for the individual and how great an economy for the State, in a material way, such prophylaxis would carry with it. When once it is generally recognized that

neuroses, even of a mild kind, in one's ancestors, may give rise to the most severe psychoses in the descendant, that the neurosis in the former is simply the formative stage of the psychosis in the latter, and that the prevention, or, if not this, the cure of the one may mean the interception of the development of the other, then the community and the State will be forced to busy themselves with the problem of the prophylaxis of functional nervous affections, and, failing in this, to give their support to means which promise relief from the existing conditions.

Unfortunately any direct prophylaxis is only partly in our power. The demand made by certain writers that we wage war against hereditary influences, and that we attempt to modify the seed of a neuropathic disposition, is futile, except in so far as has already been indicated and also in so far as treatment in itself is a prophylactic measure for future generations. Thus the questions of natural selection, of limitation of the spread of disease by regulation of marriage, of the care and mental hygiene of children with neurotic family histories, are to a certain extent utopian and too distant to be discussed in the present connection.

Yet, we physicians can do much to promote a rational rearing of children, to instruct parents and educators in regard to the noxious influence of certain external circumstances in the family and the school, to disseminate teachings on the deleterious influences of stimulants and excitants upon the developing nervous system, to promulgate correct ideas in regard to improper and premature sexual tendencies, and to establish a correct adjustment between the environment and the individual. Of most importance in the latter connection is the correct choice of an occupation, of the life work of an individual, because here, even with all due consideration for individual tendencies and proclivities, too little attention is often given to the nervous predisposition of such a person.

While, after all, it must be admitted that the question of the prevention of functional nervous diseases is intimately bound up with, and can hardly be separated from, that of their treatment and cure, it must also be admitted that in this prevention or cure of functional nervous troubles lies, to a great extent, the prophylaxis of insanity. Precisely at this developmental period of insanity, the existence of neurasthenia in one generation or another, at this most important period in the life history of a psychosis little or nothing is done. And this is so because our hands are tied! There is no place for patients with imperative concepts, for patients who are not insane, but who without proper care may easily become so, while with proper care they may be reclaimed and become useful members of society. No institution exists which will receive the neurasthenics, hysterics, or psychasthenics.

The correct treatment of a neurasthenic patient is the most difficult problem in clinical neurology. How much can be done for such a patient can be realized only when we have at our command all the therapeutic resources which study and experience have given us. Unfortunately, these resources have not received the attention from either state or society which they merit. The direct therapeutic

neuroses of varied kind has been disregarded by them, in order that the treatment of psychoses might receive the immediate attention which its importance demands. The care of other affections also—such, for instance, as tuberculosis—is occupying the attention of the public to an extent which leaves but little room for the just therapeutic consideration of functional nervous disorders. This is so because the actual menace to society and state by insanity and tuberculosis has been popularly recognized. When it is equally well understood that the large and increasing group of functional nervous affections is causing great injury to the masses and to the health of the nations, then the public will demand as its right the proper care of the broken down and nervous invalid.

This proper care must, as can easily be understood, consist primarily in the opportunity for rest and recuperation. While the treatment of neurasthenia should, so far as is possible, be a causative one, we all know that no cure can be effected without attention to the details of everyday life. The main principle of any successful treatment must be sought in the regulation of all activities, and not in the use of any single remedy or method. Occupations must be interrupted or adjusted. Activity and inactivity must be duly apportioned, the bodily functions must be regulated, habits of life must be supervised and methodized, and to hydrotherapy, electrotherapy, psychotherapy, etc., must be allotted the share which each or all combined may deserve. Above all, however, we must realize and acknowledge that no specific medicinal treatment is known and that the use of drugs can have but a symptomatic value.

Everyone of any experience whatsoever will admit that, in order to carry out the principles of treatment which here have been merely sketched, the prime requisite is the removal of the patient from his habitual surroundings, surroundings in which there exists no appreciation of the patient's condition, in which the recognition of the existence of actual disease is wanting, in which the constant admonitions to "brace up," to "exert your will power," force the patient to mental and bodily overexertion, and in which the worries about a livelihood are always dominant. Still, such a change alone will help but few.

It is being recognized more and more that these functional diseases of the nervous system can receive satisfactory treatment only in institutions especially arranged for this purpose. The majority of these nervous disorders require for their treatment such an amount of constant attention as can be obtained only in a well regulated institution, with its expert supervision and trained attendants.

Yet, we are being constantly asked, cannot the advice and the teachings which are given in an institution be written down? Cannot patients be instructed to lead the proper life, if not in their own homes, at any rate away from an institution? The answer to this cannot be too categorical. Certainly not! Teachings in advance as to how the patient should employ each moment of each day are entirely out of the question.

There can be no question about this, and every neurologist has long recognized the beam which a

well regulated sanatorium represents in the treatment of these affections; and this is true for all classes of patients, for the poor and the indigent as well as for the well to do and the rich.

In the case of the nervous or neurasthenic patient who is well to do, relaxation and supervision can usually be obtained without difficulty and for a sufficient length of time; for them there exists in all countries a large number of sanatoria, in which approximately proper care may be obtained. But the question of what is to be done for the poverty stricken patients who suffer from these same affections still remains, for this country at any rate, an unsolved problem.

Such needy patients are unable, even for a brief period of time, to meet the pecuniary demands of the cheapest of the existing sanatoriums; their earning capacity has gradually been reduced by prolonged inadequacy, and has finally become exhausted; they have sought and obtained medical counsel of all kind, but still they have at no time been relieved of their irritating surroundings, with their attendant insalubrious conditions, nagging influences, the hard work of to-day and the worry for the morrow. Is it a wonder that the treatment of neurasthenia among the poor is a heart sore to the conscientious physician?

The conditions here outlined have for a long time been recognized and their existence deplored by every neurologist and psychiatrist. Bender, Cramer, Determan, Erb, Forel, Fürstner, Jolly, Kraepelin, Krafft-Ebing, Laehr, Moebius, Neumann, and Peretti have in their excellent writings called attention to the necessity for relief in this direction, and but recently, in a presidential address before the American Neurological Association, Stedman, of Boston, has pleaded for early and efficient action. There can to-day be no question that there is a crying need for the establishment of a proper form of sanatorium for the nervous poor.

Statistical proof of the urgent need for such sanatoria has, for Germany, been furnished by Hoffmann and Peretti, who have clearly shown that such an institution would at once be filled to its utmost capacity. Such a sanatorium, in order to fulfill its mission and actually to cure a large percentage of cases, must be established upon totally different lines from those of the existing institutions for the wealthy, for it must be conceded that, with few exceptions, our present sanatoriums for nervous diseases do not produce results which are in any way adequate. Sanatorium care, as at present carried out, only too often tends toward the demoralization of the patient on account of the listless life which he is obliged to lead.

The principles which should govern the establishment and management of a sanatorium for the needy neurasthenic are those which long ago were laid down by Moebius and others, and which have since been shown practically to be correct. These principles, briefly stated, call for the proper application of rest and occupation. This rest must be physical and psychical, must be furnished by the location of the institution in the country, away from the turbulence of the city; the institution must be, as Laehr expresses it, "a harbor for those who, in the strife

and stress of the world's activities, have become shipwrecked."

But rest alone, while of the utmost importance at the opportune time, becomes an obstacle to further improvement when persisted in beyond its useful period. Then it is that the second element enters into consideration, that the weakened organ requires strengthening, and that action and activity must be superadded.

Moebius demands the "exclusion of false, harmful, or useless activity, the incitation to good, satisfactory work alternating in the proper way with rest." Even if others before Moebius have dwelt upon the value of work as a therapeutic adjunct in the treatment of neurasthenia, no one has stated so clearly as he has done that it is the *proper* work or the *correct* regulation of activity which must be the chief remedy. In an introduction to Schwartz's book he specifies his ideas as follows:

The nerve sanatorium (*Nervenheilstätte*) must be a school. The patients must learn how to live. I do not ask for a hospital, but for a school of life. If workshops are erected in a hospital and the patients are sent into them for an hour in order to let them do any superfluous work, then the work is prescribed in the same mechanical sense as bathing, massage, and anything else. That is not the way I meant it to be. The nerve sanatorium should be an organism appropriately devised and supported by the activity of all its parts, and at this useful and necessary work the patient, so far as his strength will allow, should be placed. This aim can be attained only if the sanatorium is a large landed seat, in which the work is not artificially provided, but is proffered of itself in all its manifoldness, and in which a sensible supervisor is able to give to each his own.

Thus those patients who have become nervously exhausted through overactivity or in consequence of the unsuitability of their occupation will have their new life adapted to their tastes and their capacity; they will, by means of the organization and discipline of the institution, learn what is best for them, the one being taught a trade, the other some simple office work, and the third being occupied in some agricultural or horticultural pursuit. Determan asks for still more; he wants the new profession, of whatever nature it may be, to be drilled into them until they become adepts, until they are able to compete, to some extent at least, with the healthy, and until they have thus become partially if not entirely self-supporting.

These demands may seem high, but they are practically realizable. This is shown by the history of such institutions, of such colonies.

There is still another side than the mere practical one, one which Cramer calls the "imponderable," and that is the entire social and human question which is touched by the establishment of these colonies. As Cramer justly says, such an establishment means the drying of many a tear and the relief of many a family from worry and anxiety. This plea for work, the demand for occupation for our neurasthenics, will not seem new to those of us who for years have been sending many of our patients to a ranch or to a farm, farming them out, so to say; but we shall all admit that the "proper" occupation, the "proper" work, was never found under those conditions. This plan has in my hands proved to be very troublesome and quite as ineffectual as the insufficient supervision of hygienic and

medical matters would lead one to expect. For the nervous or for the constitutional or acquired neurosthenic this plan is a failure.

Nor is the demand for work new to those who know what has for many years been done in this direction in asylums for the insane. Indeed, it seems strange, considering that our sanatoriums for nervous diseases are developmentally an outgrowth of the asylum, that the idea of occupation as applied to patients in the asylum should not sooner have been transferred to those in the sanatorium.

Yet, notwithstanding the many arguments and appeals to the public, it was not until 1897 that any practical result could be attained. In that year the fruition of Moebius's writings became apparent in the donation by a few charitable persons in Berlin of a tract of land and about \$60,000 for the purpose of founding a sanatorium for impecunious nervous patients. Hereupon an appeal was issued to a larger circle, and Haus Schönow was founded as *the first institution in the world devoted to this special purpose*.

Dr. Max Lähr was chosen director, and the first patient was received in October, 1899. Since then the movement has progressed. "Kolonie Friedau" is being organized in Switzerland; in Sachsen Weimar and Hessen negotiations for similar foundations are far advanced; in the Rheinprovinz such an institution is going up; in 1903 the "Rasemühle," near Göttingen, was organized through the efforts of Professor Cramer; most recently the city of Frankfurt on the Main has resolved to organize a villa colony for nervous diseases, and has set aside 400,000 marks for this purpose, and, finally, other countries have taken up the efforts of Germany to provide for the care and cure of the needy neurosthenic by the establishment of proper sanatoriums or colonies. Sweden is contemplating the foundation of a sanatorium upon Schönow's model, and at the Second International Congress for Assistance to the Insane, held in Milan in 1906, the following resolution was adopted:

"The congress expresses the desire to see organized popular sanatoriums for the nervous, erected in propitious locations, open to all without preliminary formalities, as is now being done in Germany."

The principles of treatment and of life in such sanatoria may best be practically studied in Haus Schönow and in the Rasemühle, and have been described accurately and in detail by Determann as well as by Grohmann.

It has been my good fortune to witness the daily régime in both of these institutions, and it affords me pleasure on this occasion to express my thanks to Professor Lähr, director of Haus Schönow, and to Professor Cramer, director of the Rasemühle, for their courtesy and extraordinary amiability in giving me free access to all parts of their institutions and in supplying me with much of the life and practical material which forms the basis of the present writing. The aim of such sanatoriums is, above all, the cure of the patient, not only in the hospital sense of the word, but also in an economic one, and the result which is sought for the patient is stable health with capacity for work and self support.

Whether this can be done or not, or whether it

can even be approximated, may be a moot question, but all plans for organization, construction, and management must be laid with this one aim in view. While the choice of a suitable location for our colony sanatorium should in a way be governed by considerations of climate, atmospheric conditions, and scenic attractions, these factors will, after all, remain secondary to the more imminent and practical ones of adaptability to the requirements as already described. For this reason a tract of land should be chosen which is made up of farm and woodland, upon which the various agricultural and horticultural pursuits to which we shall refer presently may be carried on, and which will furnish proper surroundings for the buildings which are necessary for administrative and therapeutic purposes. This land should be located upon a railroad and near a large city, not only for the purpose of convenience of access, so as easily to obtain supplies and to dispose of the products of farm and workshop, but also in order that trained assistance of a medical, technical, and pedagogical nature may be obtained, and that diversion of a suitable kind may be easily furnished. So also should the water supply not only be adequate for all hygienic purposes, but, if possible, be ample to furnish power for mills and to serve as a source of supply for the production of all the electric current that may be required.

The size of the grounds must be sufficient to furnish patients with opportunities for occupation, recreation, and treatment in the open air, in addition to offering facilities for raising products for home use, such as milk, fruit, vegetables, and a portion at least of the meat to be consumed. The acreage of the land will, of course, also be governed by the number of patients destined to be received in the institution or colony.

The number of patients thus to be received was determined by the committee appointed for the organization of Haus Schönow, and their decision was that a beginning should be made with not fewer than seventy to eighty patients; that with a smaller number classification became impracticable, the division of sexes became difficult, and the cost per capita became prohibitive. On the other hand, if too large a number of patients were to be admitted, the supervision would become more complicated and the entire organization to a certain extent unwieldy. Yet Grohmann, as well as Determann, on account of the easier apportionment of the work as well as on account of the reduction of the proportionate cost of maintenance, favors the admission of from 100 to 150 patients, and experience would seem to show that this number is the one which from all points of view can be most practically and most economically cared for. It must be evident, in view of the amount of individual attention required by each neurosthenic, and in consideration of the time which must be devoted to the psychic as well as to the physical instruction and care of each patient, that the medical superintendent, no matter how many assistants may be given him, will be unable to supervise more than this number of patients satisfactorily.

The question of economy still, of course, is an important one, for no matter how or from what source the money for the establishment of the colony is obtained, we should never lose sight of the fact

that the purpose of the institution is the care of the needy and relatively impoverished; that, even if it is designed to receive such patients as are able to pay a certain amount, in addition to those who are received gratuitously, the viewpoint is hereby in no wise changed, for the amount which such patients should pay must, under no circumstances, be so large as to invalidate the character of the colony as one designed for the care of the needy or to curtail the sojourn of those whose spirit of independence impels them to pay something. We should never forget that in many cases, notwithstanding all advantages, prolonged care presents the only hope of recovery.

In view of the fact that the class of patients to be admitted is made up primarily of the needy and destitute, we are at once confronted with the questions: What kind of patients, aside from their financial distress, should be admitted into such a colony? What kind may be admitted, what kind must be excluded? From a medical point of view there seems to be unanimity of opinion as to what classes of cases are specially suitable for reception into such a sanatorium. The proper patients are those with the numerous functional neuroses, particularly those suffering from neurasthenia, nervousness, and hysteria with its diverse manifestations. There seems to be no reason why persons with other functional nervous affections, such as certain vasomotor neuroses, migraine, chorea, etc., should not also be admitted, but it may be a question of doubt whether patients with mild hypochondriasis, melancholia, and other nervous affections belonging to the border line between neuroses and psychoses should be accepted. Certain it is that persons with developed insanity, epileptics, and those addicted to drugs cannot be received. They should be placed in separate institutions, and can under no circumstances be treated together with the subjects of functional neuroses.

Other factors than that of pure medical diagnosis also enter into the question of acceptance or rejection, and the large class of morally irresponsible degenerates, those who would prove to be a social and moral canker to the other inmates, and who are so easily recognized by the experienced observer, must not be received.

Huber has summed up this question well by formulating these rules: Patients suitable for reception must enter voluntarily, with the expressed desire for medical treatment; they must have full consciousness and recognition of their illness, and have perfect control of their own actions, in order to be able to follow medical instructions; they must not require watching, and must not appear abnormal to their fellows or infringe upon their rights.

The admission of patients suffering from organic diseases of the nervous system may be deemed inadvisable, on account of such patients' requiring essentially hospital treatment; at the same time such hospitalization of the patients afflicted with organic disease could easily be effected in conjunction with the colonization of the sufferers from functional affections, to the benefit of both classes, the one receiving their hospital treatment together with light, air, and the advantages of out of town life, while the other would thus receive the moral teach-

ings which the presence of organic disease must have upon the minds of those afflicted with functional troubles. While the entire institution might become unwieldy through this double purpose, no objection could be raised if the two institutions were associated in location, yet remained under different management.

The question has been discussed of whether both sexes should be received in one and the same colony, and, if this is done, whether they should be separately nursed and cared for. Inasmuch as the institution is to be a working one, one in which work of all kind is to be done so far as practicable by the patients, there will be plenty of work which can be done only by one sex or the other, and that would make the presence of both sexes desirable.

Grohmann also believes that the association of the sexes adds to the facility of treatment, that the men especially become more tractable, more inclined to work and exert more self control. What has been found to be the case in Haus Schönow and in the Rasemühle will probably apply to all similar institutions; this experience has been that the association of the sexes has added much to the congenial tone of the sanatorium; men and women are more careful of their demeanor and pay more attention to their clothing and appearance when under the influence of the other sex. While in the Rasemühle there is only separation of sleeping and toilet apartments, in Haus Schönow the sexes have been separated as to house, meals, and work, and partially even in their entertainments and recreations.

The question of which building system is to be adopted and what buildings are essential is of importance, yet it would go beyond the scope of the present article to enter upon these details. Certain principles of general planning must, however, be alluded to.

Thus, the system of large buildings, such as are used for asylums and hospitals, is entirely out of the question. Each building designed for the living apartments should in outward appearance and inner furnishings bear a great resemblance to a home, for the psychic effect which such surroundings exert upon our patients must not for a moment be lost from sight. The buildings must be comparatively small, should not be too near together, and should be constructed to give the impression, as Determann says, of a villa colony. He also has designated the following buildings as necessary:

1. A main building, for administrative and therapeutic purposes, containing a laboratory, living room for physicians, amusement halls for patients, etc.
2. Dwelling houses for patients.
3. A building for workshops and occupations of varied kind.
4. A central building for heat, electricity, hot water, steam, etc.
5. Agricultural buildings—farm buildings, dairy, granary.

In addition to these, a special hospital building, perhaps also one for a training school for nurses, and some sheltered promenade corridors with open front, so that patients may exercise and rest in the open air in all kinds of weather, must be considered. These corridors might be so made as to connect the various buildings.

The great advantages of such a colony system would be that a few essential houses could be erected, and these then be supplemented by others from time to time, as the institution grew in size, much of the work being done with the aid of the patients. All details of construction, elaboration of building plans, etc., must be left for discussion upon some future occasion, for the question to which we desire to give consideration now pertains more directly to actual treatment.

The treatment as carried on in such a colony will of necessity have to be of the broadest possible nature, and the principles which are to govern it must rise to the requirements set by Moebius, who, as stated, demands a school and not a hospital. Accordingly, no method of treatment must cast its exclusive impress upon the whole, and, to cite Moebius again: "That which most surely distinguishes the quack from the true physician is the one sidedness of the former. Every one who cures with a *method*, may he swear by water, or massage, or by electricity, or by nature as such, or by any other thing, is a quack or becomes one. The whole world acts so as to influence people; everything possible may be injurious, and in the same way help may come from the most varied sides."

So the chief essential of success is to find a proper head for the institution, the "true physician," who is broad minded and efficient, for everything will depend upon him; he must have a gift for imparting knowledge, must be able to teach the correct and healthy mode of life, and to bring about a reversal of ingrained habits, to recognize what the individual patient can do and what he cannot do, and to select for him the proper occupation—in short, to regulate his every action. In addition to all this, he must be a disciplinarian of the highest order.

Can such a man be found? Certainly it is no easy task, but Haus Schönow owes its success to having found such a one in Professor Lähr, and, with the example which he has set, the administration of such a colony should not be overdifficult.

In addition to the psychic influence which such a superintending physician will exert upon the patients, he must have at his command all the physical appliances which are even now found in all well regulated sanatoria, facilities for hydrotherapy, medicinal baths, electricity, massage, gymnastics, air baths, etc.; in fact, all apparatus and appurtenances for scientific and medical use. So everything which has proved of value in the old sanatoriums will be taken over into the new one. Opportunities for diversion of all kind, for summer and winter, for outdoor and indoor, must exist. Every factor by which health can be influenced will have to receive consideration in forming the atmosphere of the institution.

While the dominant difference between the colony which is being considered and the existing sanatoria is the spirit of occupation and of work which permeates the entire place, the colony being a working colony in the ideal sense of the term, "rest cure" will have their place and are by no means to be discarded. Every neurasthenic, as we have stated, exhausted, he requires rest and feeding, and

the more acute the breakdown, the more the symptoms of exhaustion and irritability outweigh the others, the greater will be the need for physical rest, for freedom from physical and psychic concentration. Yet only for a time. Soon the general principle of alternate rest and activity asserts itself, and the time comes in all cases when rest alone is detrimental; then active work, or the "work treatment," "work cure," is put into force. Here it may be said that the appellation "work sanatoriums" is a misnomer and misleading. Moebius calls it "hideous," and it should never be employed.

To this question of work we will now give closer attention; the principles as laid down and practically applied by Grohmann in Zürich, by Lähr in Haus Schönow, and by Cramer in Rasemühle are those which must serve as a basis.

It is hardly necessary to ask what work is. Yet it would seem as though many of the advocates of this therapeutic auxiliary looked upon it merely as the direct use of the muscles, as an output of mechanical energy. While this element of work, in so far as its action upon physical processes, circulatory, respiratory, digestive, and metabolic, is concerned, certainly bears an important part in the production of therapeutic results, no one can gainsay that the most important factor in beneficial work, as applied to the treatment of the nervous and the neurasthenic, is the psychic one, or deny that this factor exerts its influence not only through the negative quality of causing distraction from morbid concepts and obsessions, but also by means of its very positive qualities of producing concentration of mental processes, restoring disordered emotional equilibrium, strengthening the will, and increasing self confidence.

Too much stress cannot be laid upon the psychic effect produced in these patients by work, and for this reason the work which each person is called upon to do should have in view an ultimate object which will appeal to him, one which will be other than that only of effecting a cure. While the recognition of this curative action will exert a salutary influence, this knowledge, if unextended, would tend toward the increase of introspective and egotistical emotions; if, however, it is supplemented by the knowledge that all work has a broader object, that the work which is being done has a certain future value, and above all that this work is of actual use to the small community of which the patient is for the time a part, that the present and future welfare of the colony depend in a way upon his work, then an interest in the work will be incited and continued in many a patient upon whom purely selfish reasonings would be lost. The psychic influence here spoken of extends even to the nonworkers, and the patient who is too ill to work will profit by the atmosphere of occupation with which he is surrounded.

It has been the experience of all institutions in which work has been introduced as a therapeutic measure that most of the patients, independent of class or former position in life, will grasp at the opportunity for habitual regular occupation, and that the selection of the kind of occupation for each group of patients should be governed by that factor.

through which work exerts its greatest therapeutic effect, namely, its psychic action, the latter being effected by means of the allurements of novelty, the recognition of the curative influence, the pleasure in accomplishing and executing new things, the interest aroused by the use of novel apparatus, and, last but not least, the ethical and altruistic emotions already referred to. These considerations apply not only to the selection of the suitable work, but to the maintenance of the patient's interest in the work after it has once been aroused. While change of work may be called for occasionally and variety of work at different periods of the day may be necessary, the experience in Haus Schönow has been that it is not so much a question of variety in work as it is one of systematization and thoroughness. Of greatest import will always remain the correct instruction and the constant incitation with the most careful supervision.

The organization of the work must be begun by the selection of proper paid and trained supervisors. These supervisors, who must have the necessary knowledge, tact, and adaptability, will act as assistants in the various fields of work, will, so to say, be the leaders. They will give instruction in the manner of carrying out the technical work and will also give instruction in the general utility of work, the value of cooperation, etc. In short, technical and ethical instruction will have to go hand in hand.

It will not be long after such a colony has been in operation before these assistants and leaders can be selected from among the older patients. This stimulus of advancement is of great value, and in the course of time paying positions can be made for such patients as have shown themselves to be specially qualified and interested. In this way gradually a staff of competent instructors will be established.

The psychic aspect of treatment by occupation being of such great importance, the entire institution must be organized with the end in view of gaining and maintaining the patients' interest. The institution must bear the impress of contented work brought about by the establishment of bright, cheery, and hygienic workshops, well equipped with the necessary tools, and clean and orderly throughout.

These workshops should be sufficiently large to enable a number of patients to work with ease at one and the same time, for the comradeship of work is an important factor in gaining results. Occupation of whatsoever nature should always be carried out in company, and no patient should be put to work in a room by himself. We have already stated that most of the patients will be glad to join in an occupation which dispels the tediousness of inactivity, and it is a fact that after a prodromal and necessary period of rest, nearly all will, of themselves, ask to be allowed to work. But this beginning cannot be left to the will of the patient; when once the decision has been reached that the proper time for work has come, the proper occupation must be selected and the work medically imposed. Lähr says that in Haus Schönow but few patients were uninfluenced by the recognition of the value of work, and most of them went at it with pleasure, at first perhaps only upon medical orders; and I

myself am satisfied that in Schönow, as well as in the Rasemühle, the majority of patients work regularly, earnestly, and successfully.

Schwartz, who spent five months as a patient in Schönow, says that during the time of his stay he knew of but one patient who refused to work. Occasionally there were complaints about the work being obligatory, but every one lauded the opportunity for work. Of forty male patients in the colony in that early part of its career there were once thirty-four at work, gardening, at one and the same time; the six not working were too ill. He was astonished at the enthusiasm and perseverance which the patients at all times showed in their work.

Schwartz, who, together with Moebius and Hoffmann, is against the obligatoriness of work, certainly does not fortify his opinion by his experience at Schönow. There any patient absolutely refusing to work when ordered to do so is at once discharged, and it appears to me reasonable, inasmuch as the work is prescribed as part of the treatment, and may be modified or omitted only in accordance with the judgment of the physician in each individual case, so that the refusal to work must be viewed as an act of insubordination to medical orders, which cannot be condoned unless the discipline of the place is to be allowed to suffer.

The selection of the kind of work best adapted to the need of each patient is not an easy matter, but can usually be properly made by the application of the principles already described. Before such choice is made the decision must, however, be reached as to whether manual occupation or some form of brain work is preferable. It has been said that this choice will depend upon the nature of the work which has led to the breakdown; that in the case of brain workers brain activity is to be reduced or excluded and muscular work substituted, while the manual worker is to be interested in a more or less psychic way.

We, who believe that the chief therapeutic value of work, whether of brain or of body, lies in its psychic influence, cannot accede to this view without modification, for it must appear to us that in the vast majority of cases preference is to be given to some form of manual work, regardless of the previous habits of the patient. This is so because manual work carries with it a direct action upon the somatic processes, in addition to its psychic influence, and because most patients, whether head workers or hand workers, have been accustomed to some form of manual occupation from early life, and it will be easy to accustom them again to do that which they did in their childhood; in addition to this, there can be no question that manual work can be more easily organized, supervised, and controlled.

The fear expressed that purely mechanical work would be devoid of interest to the head workers, from which class the majority of patients are recruited, has been controverted by practical experience. This has shown that in the existing colonies the most enthusiastic workers in the shop and garden belong to the intellectual class.

On the other hand, when manual work is chosen for former hand workers, the patient ought not at

once be put to work at that which has constituted his own trade. As soon as that is done the entire psychic effect of the work is lost; the work with which he is so familiar, and which has been a factor in his breakdown, will to him be nothing but "work," and counteracting suggestions of manifold nature will neutralize the suggestion which we had hoped to impart.

Care should, of course, be exercised lest the patient overdo, for, aside from the fact that in all neurasthenics there exists a pronounced exhaustibility, those patients who have hitherto done nothing but brain work, and have led a more or less sedentary life, have no gauge for their physical capacity and are apt to overexert themselves. Careful supervision, especially under proper observation of the pulse rate, will here be the chief protection against exhaustion.

Under no circumstances should physical exercise be looked upon as a substitute for physical rest. The evil effects of mental overexertion can never be counteracted by muscular activity, and bodily work as such is no remedy for fatigue of any kind. The practise of recommending physical work as a neutralizer of mental fatigue can only be characterized as pernicious.

The choice of the special kinds of occupation to be used in the colony will be met by the principle of the greatest good to the greatest number, and the result of experience has been that this requirement is best met by two kinds of work—these are carpentering and gardening. Both of these combine the psychic and mechanical factors essential to successful therapy in a greater measure than any other kinds of work.

Carpentering especially is of very great value; in no other occupation are mental interest and muscular activity combined as they are here; according to the kind of work done, sawing, planing, or hammering, all movements of the body may be obtained in any relationship and to any desired extent.

At the same time the result of the work soon becomes manifest, for in a relatively short space of time some useful object may be produced; the work is concrete, it may be surveyed from beginning to end, and thus psychic interest be maintained.

To gardening, as Grohmann has shown, must be given second place; its disadvantages lie in the psychic reason that it is not sufficiently concrete to be surveyed and learned in a few months. The period of growth of most plants is too long to enable patients to obtain a general view of the connection between their daily task and the total result. But the factors which go to make up gardening as a whole, the digging, hoeing, raking, cutting, etc., are all of inestimable value. For this reason the simpler forms of gardening are of greater service than those of higher grade.

While carpentering, gardening, or agricultural work will constitute the chief sorts of occupation, other forms must also be employed. For those patients in whom no interest can be aroused in carpentering or gardening, or who for one reason or another cannot or may not take part in these pursuits, some supplementary work must be furnished.

Bookbinding, scroll sawing, pyrography, drawing, modelling, wood carving, designing, photography,

decoration of pottery, or clerical work will serve as the means to our end. In Haus Schönow, bookbinding has proved to be a suitable occupation for many patients and is utilized for an hour each day, under the supervision of a patient who has been specially taught and with the assistance of a professional bookbinder who does not live in the colony. Thus, in 1903, 124 books were bound by patients for the colony's library.

Typesetting and printing are also done there, and upholstering in all its branches has, by its diversity and evident results, given pleasure and occupation to many patients. Basket making and analogous occupations, which have been recommended by many and which are much employed in colonies for other classes of patients, are justly characterized by Grohmann as "stupid."

Female patients will also find fruitful sources of activity in the necessary household duties and kitchen work of varied kind. It would be futile to enter here upon the details of all of the various kinds of work which may prove serviceable or to attempt to plan too much ahead of the actual establishment of the colony; much will develop of itself, much will show itself during development and growth which cannot be foreseen and which will be adapted particularly to the individual colony which has been organized.

Above all, however, let us bear in mind that the work as planned and carried out in institutions for the insane should not, as has been advised, be transported as such into the colonies for neurasthenics. No matter what the nature of the work made use of, we should always remember that every treatment by means of occupation has its limitations, and that the indiscriminate use of such treatment necessarily carries with it the dangers attendant upon indiscriminate of every nature.

If new colonies are to be established upon the aforesaid or similar lines, and of the crying need for their existence in every State of the Union there can be no question, we must ask ourselves the practical question, Who is to furnish the means for their organization and support?

That the State would profit greatly by the establishment of such colonies has already been shown, and that State prophylaxis and State hygiene are rights which the people can demand has been acknowledged by the State through its work in every other direction. The State must aid in maintaining the physical and psychic availability of the individual, for the assets of a nation are made up of this physical and psychic productivity of its individuals.

On the other hand, the State can hardly be appealed to for aid until the practical proof of the necessity and benefits has been furnished, and it is even questionable whether it would be wise to seek State support in the beginning. The institution being essentially a charitable one it will be found that the impressible neurasthenic will be more willing to place himself under treatment, and will do so with greater freedom of mind, if the colony is the outcome of private charity than of a State charity. In the latter case the parallel between asylums and workhouses would be very close.

Private charity will here, as it has so often done before, once again have to lead the way. I cannot

quite well that the demands made upon such private charity are enormous, and that individual donors are appealed to for aid from all sides and for all purposes; yet, when once the worthiness of such an institution has been proved, there should be no difficulty in obtaining even more than the necessary support from all classes of society. The history of the European colonies shows that we should have no misgiving as to the possibility of obtaining the necessary financial support. What has been done abroad with difficulty should be accomplished here with ease.

In conclusion, I would say that any description of the entire organization and equipment of such a people's sanatorium for functional nervous affections would give one the impression of great complications and unwieldiness of management. This impression is, however, at once dispelled by a personal inspection of the existing colonies. It is entirely a question of initiative, growth, and development.

## THE MOST USEFUL SPECIALTY IN MEDICINE

*To Estimate the Vital Status and Enhance Efficiency by Eliciting Contributory Agencies in Reestablishing Autoprotective Equilibrium.*

By J. MADISON TAYLOR, A. M., M. D.,  
Philadelphia.

No form of medical specialism can accomplish so much as one which aims to reinforce inherent energies, to perfect latent or impaired powers. It is but a limited conception of professional duty to be content to merely repair damages or injuries, to overcome the effects of disorders, or even to cure actual disease. In the field of restoration large individual abilities are exhibited by the exponents of restricted specialisms. The best effects are, even there, due to the measure of wisdom shown in dealing with the broader factors involved in supplying constitutional needs. The solution of most of these problems often lies in estimating the exact status of the grosser mechanisms and in correcting many contributory disabilities not ordinarily recognized as significant.

Every person, young or old, is capable of a notable increase in vital status by revising modes of life. This is particularly demonstrable as middle age approaches and tissue elasticity subsides. Some of these deviations merge into serious retrograde changes, often shown by rigidities, densities, caused by faulty habits or vitiated automatisms, due to omissions of suitable variety in both impulses and movements, whereby alone symmetrical action and reaction are assured. The factors involved are both psychical and physical. The deadening effects of routine, of monotony, are well known. Stimuli should be varied; suggestion or autosuggestion is rarely adequate to preserve rhythm. Individual resourcefulness is seldom large, or only exhibited in restricted and specialized lines. Hence it is of value to invite skilled direction from one who has achieved a well rounded familiarity with human perfectibility, needs, and derangements, and can judiciously particularize.

Human health, constituting, as it does, the basis of economics, is steadily coming to be recognized at its true commercial value. Bread winners especially are awakening to this fact, and beginning to appreciate expert professional aid in perfecting and maintaining bodily efficiency. That physician is most wise and useful who omits no opportunity to estimate the fundamental factors in any problem presenting. Not only should he meet immediate exigencies, deal correctly with confronting difficulties, but search out and correct underlying and contributory causes, which may keep the individual on an inferior plane of potentiality. He should do much more; make occasions, seek earliest possible opportunities to learn all relevant facts bearing upon the vital status of those in his charge. To accomplish this the public requires constant and varied education. The tendency is for each good citizen to make the best of his condition, to treat lightly unobtrusive ailments, to forge energetically ahead, ignoring slight symptoms, especially psychical phenomena, so that, too often, serious states are only revealed when far advanced or too late. This disregard of ailments is commendable; it makes for renown, for character

building, for success. Through such pertinacity only are the highest ends achieved. Carried to its logical limit, however, it lures the ignorant optimist to a state of perilous monism. Conversely, to err by overmuch selfsearching leads to hypochondriasis, timidity, inefficiency. Most physicians are aware of this, but there are different degrees of awareness. Some impressions, even some convictions, are cloudy, inexact, or, worse, fail to act as stimuli to right action. A nicety of judgment is needed in solving such problems. For instance, it will prove a boon to a man complaining of a slight dyspepsia for the physician consulted to discover and rehabilitate an organism never brought to that degree of vigor and stability which, if attained, would have enabled him to become a power. Hitherto he may have been held by removable limitations to some petty, hiring post.

Numberless men and women often courageously and intelligently undertake ventures well within their inherent powers, who are yet not able alone to bring them to full fruition. They may be handicapped by physical defects, wasteful in method, underdeveloped, lacking in some essential particular, or all these combine to keep them low in the economic scale. Unwarned, confident, they often assume increasing burdens and press on to, or beyond, the limit of their working powers. There then ensues some minor or major accident, and a useful life is warped, mind and body are distorted, perhaps thereby also complicating important collateral domestic or financial interests. All this dwarfing could have been avoided by adopting one of two courses of action: (1) Had the family physician been observant, wise, and, above all, dominant, corrective measures could have been instituted sufficiently early; or (2) had the individual been duly alive to his economic needs, advice would have been sought capable of establishing full working efficiency.

It is true that the general practitioner, hampered as he too often is by a multitude of fatiguing exactions, harassing exigencies, may not be expected to accomplish more than he does. Too frequently, however, his interest is exhibited rather in the immediate than in the basic problems.

Admitting the force of the proposition suggested, there would seem to be ample work in any community for specialization in *systematic amplifications of efficiency*. The chief difficulty, as in all specialisms, is the petty distrust and jealousy which discourages frank consultation, cooperation, except in departments of professional effort rigidly defined.

Another serious difficulty is the supineness of the profession in omitting to *compel recognition of the high pecuniary value of expert advice in the conduct of life*. The general public are not slow to realize the value of first class working efficiency, however blind individuals may be to their own ultimate advantage. For the relief of actual disease or damage, even more so for fancied ailment, they are often willing to consult a physician. When people arrive at the conviction of a need for general or special betterment, they are usually prepared and willing to spend time and money on measures con-

fidently endorsed. Hence much capital is invested in various medical enterprises, good and bad, legitimate and quackish. If, however, they would realize that the best, the most complete, plan is to promptly and frankly consult a physician, or to seek advice periodically as to how they may retain their health, improve their powers, achieve a relative perfection, by far the greatest gains in efficiency would follow.

Furthermore, should objection be raised to this unusual course of action, practical analogues can be shown to obtain in many other lines of professional activities as in manufacturing, engineering, or mercantile lines. Specialists flourish, earning large sums, who are employed to revise existing business methods, suggest improvements, promising the enhancement of organization, economics, and earnings. I know one gentleman, a mechanical engineer, who in early middle life adopted this improvement specialty much to his own financial advantage. There are many such in other lines. This form of specialization is preeminently a practical one, and within the capacity of many. It requires thorough technical knowledge and a broad grasp of details and policies. Lesser business specialists there are in plenty, competent in narrower lines; experts in mechanics, in chemistry, in labor saving devices, in advertising methods, in the search for markets, etc. These are the analogues of our specialists in diseases of the eye, ear, throat, skin, heart and lungs, kidneys, rectum, etc. Busy they become, satisfactory earnings do they make, valuable services do they render. Yet wherein does this detail service compare to that of one who, having all these and other resources at command, shall, with their aid when needed, estimate the organic index, the structural, the circulatory balance; ascertain the significance, by expert estimation, of developmental faults, of significant maladjustments, of the phenomena and effects of vitiated physical habits, motor, sensory, psychic, and the like?

One of the most important points is to determine and adjust the kind and quality of mental impulse, present or needed; the capacity for psychical right direction and persistence.

In the process of enhancing vital powers there are diverse, well known, excellent resources, often wisely employed. These embrace such familiar measures as regulation of life on a hygienic basis, including all those factors which contribute to physical economies, to normal activities, as by open air life, dietetic care, correction of functional or constitutional errors by well chosen drugs and the like.

These are efficacious in proportion to (1) the judgment and care exercised by the adviser in searching out causes, and (2) to the degree of cooperation supplied by the individual. Success depends upon a thorough estimation of the specific needs of each person.

The possibilities of such specializations may be rendered clearer by one or two illustrations, combining certain supplemental measures which have often contributed materially to my own successes, viz., the correction of conditions which may be described as *dysmetries*, but which really constitute

the foundation of many metabolic disorders and demand orthopaedic treatment.

A long experience in and many consistent endeavors to solve the complex problems of patent but indefinitely lowered health, to get that uplift so desirable whereby we may make efficacious previous efforts, has impressed me with the importance of securing greater elasticity of the tissues and promptitude in the reaction times between controlling centres and outlying motor parts. This constitutes a key to vascular competence, by enhancing vasomotor reflexes throughout the whole system. The grosser mechanisms often need even more attention than is afforded by customary methods of organic regulation, because without first achieving elasticity therapeutic results are not so readily secured. *Full organic competence is not sustainable unless the supporting structures are maintained in normal degrees of mobility.* The lungs, heart, etc., for instance, cannot do their perfect work in a contracted thorax. The abdominal viscera are unable to perform their full duties unless their supporting structures are adequately strong and elastic to exercise normal counter pressure. The hollow viscera both above and below the diaphragm need to be held poised in the normal interrelationships, so that vital hydraulics, connecting tubes large and small, suffer no interference from undue compressions. Poisons, endogenous and exogenous, work greater harm unless local stasis is relieved. No amount of salutary passive conditions can accomplish much if the normal stimuli to circulation lack something of necessary impulses and responses. The most powerful drugs can do little for ultimate restoration of capacity if the great oxygenating laboratories, the muscles, cease to do their essential cooperative part.

The subsidiary centres in the spinal cord, regulating vasomotor action, require that the paravertebral tissues shall continue to receive normal stimulation. So simple seeming a measure as making more flexible the backbone is followed in my experience by extraordinary betterments. There are thus provided structural normalities in the reflex cycle to motor stimuli through the vasomotor cell bodies in the corresponding segments of the cord. Hence the ebb and flow of fluids is encouraged. The physiological factors in this reflex process I have often outlined; the clinical proof is daily seen in my work.

Paraphrastically let me say that the benefits which we know to follow physical activities are explainable upon this same principle of responsiveness to reflex motor stimulation through vasomotor subcentres. For those who are unwilling, unable, or organically unfit to avail themselves of open air sports, muscular activities, as much or even more can be accomplished by brief but exact education in the cycle of motor impulses and responses, along with correction of local rigidities in the skeletal structures, direct or collateral. There is needed a precise estimation of what is amiss in the particular person, by whatever means the individual taste, opportunities or organic competence makes practicable, and correcting, in so far as is feasible, the observed shortcomings.

*By securing greater elasticity of the less used structures we can accomplish improvements in many unexpected directions, among the chief of which is securing harmonious interreactions through systematic motor stimulations.* The body is dependent upon wholesome motor stimulations for the maintenance of diverse nutritive processes. The paravertebral tissues are, as has been said, innervated by the posterior primary divisions of the spinal cord; mechanical stimulation of these structures causes salutary reflex vasomotor effects, through the cell bodies in the segments inducing pronounced circulatory quiescence or enhancement. Derangements in organic or other peripheral tissues always induce alterations in the nutrition of the cell bodies from plus or minus afflux of blood. These are almost always recognizable through alterations in the gross morphology of the erector spinæ muscles and of the ligaments. *By encouraging activities in these paravertebral muscles, and securing elasticity in the ligaments in the back, there follows, in my experience, a corresponding and correlated enhancement of all organic activities.* This can be readily accomplished by systematic posturings, torsions, bendings, etc., alone or along with extensions of the limbs and systematic forced respiratory acts, whereby the junctures of the ribs and backbone are made more mobile.

Indeed, oftentimes a larger benefit follows from a ten minutes daily practice of such stretchings than from hours of ill directed "physical culture" stunts. Take an instance, oft recurring, where the chest has become rigid, usually contracted, the neck tissues also. It is a principle evolved by my experience that *normality of posture is essential to organic competence.* Erectness is compounded of vertical and horizontal lines from which diverse other lines may depend. While curving lines make for grace they tend to impair the power of support. The weaker the person the greater are the curves exhibited. Much bodily weakness is conditional upon that exaggeration of dependent lines which evidences incompetence in the supporting structures. These supporting structures may be at fault, both at origin and periphery. For example, the visceroptosis, as I have repeatedly emphasized, arise in central defects which can and should be radically corrected by enhancing the vital index through attention to the inherent fountains of force.<sup>1</sup> A secondary cause is loss of integrity in those agencies exercising support which is supplied by collateral and external structures. Where these are voluntary muscles their vigor must be enhanced by all means, among the most definite of which is suitable use by exercise.

*The key to erectness, hence of skeletal efficiency, hence of visceral interrelationships, hence of an important factor in organic competence, lies in the maintenance of a normal posture of the thorax.* This assumes the maintenance of a relatively straight backbone and horizontality of ribs. When the ribs remain relatively hori-

The principles of organic action, as made plain to the first time by Chas. F. de M. Taylor, in the *Internal Secretions*. The dominant agencies are the ductless glands, the adjuvant system.

zontal and are easily held well up to their normal levels, there is thereby afforded adequate support to the diaphragm, the external and internal abdominal muscles, and to all those structures combining to afford visceral support. There is thus afforded a surprising degree of improvement in organic competence.

To secure this thoracic normality requires intelligent motor education. By the simple device of training a patient to clasp the hands behind, pulling apart strongly and pushing the arms forcefully down, at the same time thrusting up the chin vertically, these contracted tissues are forcefully stretched, perhaps for the first time in years. This act repeated, and with steady increments of force, widens the front of the thorax, educates the down pull of the erector spinae muscles, and overcomes the common and damaging habit of stooping. Stooping always induces undue compression of the larger viscera.

By this procedure I have been able frequently to rid patients of limitations caused by adherent pleura; to improve the power and sonority of the voice; to restore in a measure chronically impaired hearing; to relieve many of the evil effects of chronic heart disease; to mitigate asthmatic states, etc. The increased respiratory capacity induced also makes for many æsthetic as well as essential betterments. By adding to this (the most efficient known "setting up" device) forced expiratory action, the lower ribs being made to forcibly contract, the abdominal contents are raised toward the diaphragm, hence a varied train of advantages ensues. In short, by a close study of the minor contractures and their economic corrections, it is practicable to achieve that symmetry and elasticity of the body, at any age, which constitutes the index of working capacity.

One eminently satisfactory and unexpected result has followed in a dozen instances from voluntary elasticizing of tissues, viz., improvements in progressive deafness. The description of one case will serve to illustrate.

A lady, sixty-nine years of age, had steadily lost sense of hearing, being told by the best otologists that it was due to inevitable, unchangeable changes aggravating catarrhal processes. She was a vigorous, massive woman, over red, presenting distressing phenomena due to passive congestion of the head. In my efforts to relieve the obvious tissue waterlogging, I trained her in neck stretchings, torsions, forcible chin elevations, etc. Also I adopted hints from a Viennese laryngologist, in an article on treatment of chronic catarrhal conditions, to forcibly open the mouth, simulating the act of yawning, all with the purpose of so stretching the stiffened tissues as to invite afflux of blood to impoverished muscles and adjacent structures.

To my surprise and gratification the hearing steadily improved. Now, at the age of seventy-seven, this lady can hear about twenty-five per cent. better. Many similar results have followed like efforts, success being in proportion to intelligent cooperation and persistence.

Such a careful study of individual defects, inherent or acquired, as are here instructed, and their judicious correction, using resourcefulness in not only removing but enhancing the existing strain by rational auxiliary measures, affords full scope for a specialty to which none other can be superior.

—UOPI PINE STREET—

## THE PALLIATIVE TREATMENT OF PROSTATIC HYPERTROPHY.\*

By FREDERIC BIERHOFF, M. D.,  
New York.

Attending Surgeon, Urological Department, German Dispensary,  
Fellow, New York Academy of Medicine, Corresponding  
Member of l'Association Française d'Urologie, etc.

When our president invited me to address this society, he suggested that I take, as a topic which would be of interest to the general practitioner, the palliative treatment of prostatic hypertrophy. In accepting his invitation, I accepted also his suggestion regarding a topic, for the reason that I have long felt that the possibilities of palliative treatment in cases of prostatic hypertrophy have been rather overshadowed by the enthusiasm felt by the general surgeon for radical operation in this disease condition. I do not wish to be misunderstood. There comes a time in the history of almost every case of true prostatic hypertrophy when a radical operation is demanded; but I also feel certain that the indications for operation and the contraindications forbidding operation are not sufficiently studied by the general run of surgeons, and that they often lose sight of the not inconsiderable risk which always accompanies so grave an operation as the extirpation of the prostate in their enthusiasm over a certain type of operative procedure. Some of the cases which I have seen and examined, after a considerable lapse of time following radical operations, have made me think that they would have been better off had the means employed been palliative rather than operative. I firmly believe that the *true* statistics of radical prostatic operations have not, as yet, been written. The temptation to class cases as cured, when, a short time after the operation the patient is free of symptoms and discards his catheter, is very great.

We must not forget, on the other hand, that there is a large percentage of cases in whom, for various reasons, it is an impossibility for the patients conscientiously to carry out the various measures necessary for a successful palliative treatment, and that, in these instances, radical operative treatment should be the choice, as being the lesser of two evils.

Leaving aside any consideration of the question as to whether true hypertrophy of the prostate is of inflammatory origin, or of true neoplastic character, we may pass to the classification of the stages of prostatic hypertrophy as we see them in practice.

The first stage—the premonitory, or developmental—is characterized by the conditions that the bladder is still able to empty itself, practically completely, and that the patient complains, chiefly, of an increased desire to pass water, and increasing tenesmus, which develop into an imperative desire to urinate, and, finally, of a difficulty in passing water. The first symptom which usually affects a patient and draws his attention to the fact that his bladder is not normal is the development of a desire to urinate frequently during the night. He must get up once or twice during the night, or, at least, as this stage is seldom complicated by cystitis, the nocturnal is not marked. The patient usually promptly falls asleep, after having emptied his bladder, and his general condition is not materially affected. The

eral condition is little impaired. Usually the amount of urine passed at each micturition is rather small, but there may be a true nocturnal polyuria. A frequent symptom during this stage is that the patients complain of a burning pain, which they locate a short distance behind the glans penis. The ability to start the stream of urine is also somewhat impaired, and the stream itself is rather smaller than formerly, and weaker. These symptoms are, in great part, due to congestive conditions of the prostate and prostatic urethra, and we frequently meet with sphincteral spasm, which shows itself by an interrupted jet of urine, a few drops, or a teaspoonful being ejected during each act of micturition. The fact that the symptoms are more pronounced during the night is ascribed to an increased congestion, or hyperæmia of the prostate, while the patient is in a recumbent position. This condition also explains the frequent occurrence of painful erections during the night. During this stage any conditions which tend to increase pelvic congestion increase the symptoms, particularly the dysuria, very much. If we examine patients in this stage, we are frequently surprised at the comparatively slight degree of hypertrophy palpable upon examination per rectum. The prostate is only slightly enlarged, and is of a moderately elastic consistence. The insertion of a catheter usually meets with a distinct sensation of obstruction when it enters the prostatic urethra, and its passage is usually accompanied, at this point, with considerable pain. The amount of residual urine in this stage is usually small, 15, 25, or 30 c.c. being a fair average. Examination with the cystoscope reveals but slight hypertrophy of the gland, with, in almost all instances, little or no evidence of hypertrophy of the bladder muscle, and no inflammatory changes. I have, however, repeatedly seen unusually prominent veins just at and about the vesical neck.

It is during this stage that most can be done by palliative measures. The patient should be carefully instructed concerning his mode of life, and the necessity for his bearing in mind the fact that his prostate is not normal, and that he must regulate his life and his habits to conform with the needs of his condition, is imperative. It must be borne in upon his mind with emphasis that whereas, with care upon his part, he may live in comfort for many years, his prostate and bladder are his points of least resistance, and that every indiscretion or carelessness of which he is guilty will show itself in the increased symptoms from which he suffers. Such patients should be instructed to avoid, above all things, sitting for long periods, long drives, or long rides in railway carriages; horseback riding, in particular, must be avoided. I have made it a rule to advise men whose work is of a sedentary character, under such circumstances, to use an air ring upon their chairs or seats. They must avoid excesses in eating; avoid alcohol, spices, or highly spiced foods, exposure to cold and wet, and must attend to the condition of the bowels, and arrange for regular evacuations daily. Where cathartics are necessary, mild medicaments, such as cascara, epsom salts in moderate doses, castor oil, or some of the mild aperient waters are preferable. The patient should dress in such a manner that sudden changes in temperature may

not bring on chilling of the body. I advise patients of this class to wear natural wool underwear, in different weights, during the entire year, and also to avoid wetting of the feet, or sitting down upon cold or wet ground. Sexual intercourse, in moderation, is not harmful, but all sexual excesses are strictly contraindicated. These patients should be instructed, also, that should complete retention occur, at any time during the course of their trouble, they may employ a hot sitzbath, of from five to ten minutes' duration, and attempt to urinate while seated in the bath. In fact, I have found the hot sitzbath, used at night, just before the patient retires, a routine measure of great help in lessening the prostatic congestion, and have frequently been surprised to note the marked relief which such a simple measure procured for the patients during the night. They should also be instructed that in case of sudden, complete retention, they must not delay long before sending for their physician, but that if the attempt to urinate while seated in the hot bath fails, they should at once send for their medical attendant and permit him to draw off the urine by the catheter.

Where the compressor and sphincter cramp is pronounced, the careful passage of a metallic instrument is advisable. Many authors speak of the passage of a metal sound in these cases. Personally, I prefer to use a metal *catheter*, of a size corresponding to the sound, because of the lessened danger of making false passages. The manoeuvre which I always employ in such cases is as follows: The glans penis and prepuce are thoroughly cleansed with a solution of bichloride of mercury, 1 in 4,000. The anterior urethra is then irrigated with a solution of 1 in 20,000 bichloride of mercury, after which the attempt is made to inject a small quantity, the amount of which is noted, through the posterior urethra, into the bladder. Where the compressor cramp is pronounced, 8 c.c. of one per cent. cocaine solution is now injected into the urethra, and the urethra gently manipulated in such a manner that the solution is forced into the posterior urethra. After superficially anesthetizing the posterior urethra in this manner, a cleansing fluid may be injected through into the bladder. The catheter, sterilized by boiling, is now gently passed into the bladder, and the appearance of fluid, escaping from the catheter, is positive proof that the instrument is in the bladder. The bladder is now thoroughly cleansed with tepid one per cent. boric acid solution, and the catheter allowed to remain in place for a few minutes and then withdrawn. Some authors advise the use of posterior urethral dilators in cases of this sort. My personal preference, however, is for the metallic catheter, as before mentioned, for the stated reasons.

The most frequent complication of this stage of the disease is complete retention of urine, following, usually, some breach of the before mentioned regulations for the general conduct of the patient. This may be treated by rest in bed, and by intermittent catheterization; but should it persist, I believe the preferable treatment to be the *cathéter à demeure*. This may be left in place for several days, under aseptic and antiseptic precautions, and its use is generally quickly followed by relief of the acute retention.

Out of this first develops the second stage, or stage of vesical insufficiency, due to the gradual weakening of the muscle fibres of the bladder wall. This stage is characterized by a chronic, incomplete retention of urine. The symptoms which present themselves during this stage are, in the main, exaggerations of those present in the first stage. Added to this are the symptoms resulting from the accompanying cystitis, which, sooner or later, develops in all of these cases. I have been surprised, however, in many cases, to find how long a period will pass during which men, with marked retention, will maintain urine which is practically normal. The intervals of rest between the imperative desires to urinate grow shorter. During the day the patients urinate at intervals, frequently as short as an hour. The sensation of burning and of tenesmus is increased. The stream of urine grows weaker and smaller, even at times flowing merely in drops. The patients also complain of an increasing pain in the region of the glans penis, and of an uncomfortable sensation, as of a foreign body, in the rectum. Obstipation is increased. The patients pass stool which is thinner than the normal, and sometimes flattened, and prolapse of the rectum or the formation of hæmorrhoids are not of infrequent occurrence as a result of the severe straining to evacuate the urine. During the night, particularly, the frequency of urination is increased, the intervals being even so short as a half hour. During this period also the patient's general condition suffers; digestive disturbances result, and mild febrile movement may occur. Owing to these various general disturbances, and, in great measure, to the disturbance of the night's rest, the patients grow weaker, and are less able to ward off complications. Here, too, vesical or urethral hæmorrhages may occur; cystitis is very likely to result, and an infection of the kidneys or pelvis may occur. Polyuria is not an infrequent development during this stage. This second stage develops either suddenly, as the result of an acute retention of urine, or it may come on slowly. Palpation of the prostate now reveals a rather markedly enlarged gland, and the cystoscope shows a prominence of the lateral lobes, or the middle lobe, or a combination of these. The lengthening of the prostatic urethra is also more pronounced. In addition thereto, the cystoscope usually reveals a condition of columnar bladder—more or less marked hypertrophy of strands, or bundles of bladder muscle, with spaces of weakened bladder wall between them. We also here frequently note the development of diverticula. There is usually, also, an accompanying hyperæmic or inflammatory condition of the bladder wall, which is more marked in the region of the trigone and the vesical neck. Here, too, we frequently see a varicose condition of the vessels at the bladder neck. The most important requirement of treatment during this second stage is systematic and regular emptying of the bladder by catheterization. The tendency toward too frequent catheterization, however, must be combated. Where the patient has a residual urine of between 150 and 200 c.c. it is usually sufficient to empty the bladder once during the course of the day. The time for this catheterization is preferably at night, just before the patient retires to bed. In this manner he is insured a longer period of rest during the night.

Catheterization, whether performed by the patient or by the physician himself, must be done with the greatest care and gentleness. It should be borne in mind that the powers of resistance of these patients are diminished, and that any lesion of the urethral canal or of the bladder is, almost invariably, followed by a reaction, which only tends to further sap the patient's vitality. It is a good rule to keep the catheter out of the patient's hands until this is no longer possible, unless he is a man of sufficient intelligence to fully appreciate the need for the greatest possible care.

In the choice of a catheter I am usually guided by the presence or absence of resistance in the posterior urethra. I prefer not to manipulate long with a soft rubber catheter, but usually at once pass to the flexible silk, or linen catheter, with the single Mercier beak. Care must be taken that the catheter has a smooth exterior, that it is sufficiently flexible, and that the catheter eye has no rough or sharp edges. It should invariably be boiled for at least two to three minutes before being used. Boiling in this way, in plain water, does not hurt catheters which are properly made. Many of mine have been boiled fifty to eighty times or more without injury. A catheter should never be inserted until after a preliminary irrigation of the anterior and posterior urethra, with 1 in 20,000 bichloride solution, and until the glans penis and prepuce have been thoroughly cleansed with 1 in 4,000 bichloride solution. The catheter should always be passed with the patient in a recumbent or semirecumbent position. The hands of the person handling the instrument should be thoroughly cleansed, and the catheter seized at a point close to the outer end, so that that part which is to enter the urethra and bladder may not become infected through handling. A sterilized lubricant is used to anoint the catheter, and it is a wise precaution to express and wipe away the most superficial layers of lubricant in the tube, and to cleanse the mouth of the tube containing the lubricant before applying it to the catheter. It is well, too, to pass the mouth of the container through an alcohol flame a few times. The catheter must now be gently inserted, the left hand of the operator steadying the penis, and the catheter gently pushed forward until the urine flows off, care being taken to keep the point of the beak directed upward. If, upon emptying the bladder, bleeding occurs toward the end of the act care should be taken not to let the bladder empty itself fully, but to replace some of the urine with sterilized boric acid solution, until the fluid flows off clear, and to allow about 50 to 100 c.c. of boric acid solution to remain in the bladder, according to the amount of residual urine it contained. The urine should never be withdrawn from the bladder without a subsequent irrigation with sterilized boric acid solution, no matter how frequently, during the course of the day, catheterization is resorted to. Where cystitis is present, the cleansing irrigation may be followed by the use of a solution of silver nitrate, beginning, usually, with 1 in 2,000 and increasing, gradually, to 1 in 1,000, or even 1 in 500. Although this may cause some tenesmus, it is usually of short duration, and is, in most instances, quickly followed by marked relief in the inflammatory symptoms. In addition, the hot sitz-

baths, previously mentioned, are of service. Internally, urotropin, helmitol, formin, or any other of the reliable formaldehyde combinations, should be employed, in order to diminish, as far as possible, the bacterial contents of the urine. Where tenesmus and rectal discomfort are pronounced, a rectal suppository of opium and belladonna, or a small enema of hot water is frequently of benefit. Frequently patients may be carried over years, in great comfort, by carefully carried out and consistent catheterization, with the accompanying measures of treatment. Particularly is this the case in those patients in whom some contraindication to operation exists, such as marked atheroma of the vessels.

The third stage is that of complete retention, with, in some cases, ischuria paradoxa. In this stage the desire to urinate reaches a frequency, in many instances, of five to ten minute intervals, both day and night. All the symptoms previously mentioned are increased in their severity, and the patient, in spite of persistent attempts to urinate, is unable to pass any urine whatsoever. It is during this stage that toxic symptoms are likely to develop, owing to resorption, and to involvement and dilatation of the ureters and kidneys. Polyuria is also pronounced during this stage of the illness, and five to six quarts of urine during the twenty-four hours may be passed. This is usually due to secondary degenerative changes in the kidneys. The gastrointestinal symptoms are increased, and febrile movement, accompanied by chills, is not of infrequent occurrence; cerebral symptoms pointing to a uræmic condition are not unusual, and hæmorrhages are frequent. Even here, in many cases, regular, carefully carried out catheterization, combined with proper general treatment, may serve to tide the patient over the grave condition and make him comparatively comfortable. Particularly is this true of the use of the *cathéter à demeure*.

In addition to the measures previously mentioned in the consideration of the different stages of prostatic hypertrophy, general tonic treatment is indicated during the entire course of the illness. The condition of the skin, also, must be kept good by regular bathing, such patients doing well to use warm body baths twice a week, followed by brisk friction over the entire body. These baths are best taken just before retiring at night. Attention must be paid to all intercurrent disturbances, particularly those of the digestive tract.

Of direct measures, not radically operative in character, numbers have been suggested. Direct electrolysis of the gland, the negative electrode being inserted, through the rectal wall, into the substance of the prostate gland, the positive pole being placed upon the abdomen, gave little, or no, benefit, and was, in a number of instances, followed by unpleasant complications. Injections of drugs, directly into the perenchyma of the gland, have been similarly unsatisfactory. Faradization has been tried without success. The x ray has also been employed without much benefit. Massage of the gland itself has been of little benefit, except in such cases as were due to chronic congestive causes. In several cases of this latter type, however, I have felt that my patients obtained much benefit therefrom.

Naturally, where we are dealing with a fibrous prostate, massage of the prostate can be of no value. General massage, however, particularly when applied to the lower abdomen, the thighs, and the pelvis, has been reported as being of distinct benefit in many instances. Organotherapy, which has been tried in a number of instances, has been without any benefit.

Where hæmorrhage results, as not infrequently happens in cases of prostatic hypertrophy, and where an acute retention develops, or where a pronounced cystitis, or a pyelitis, or pyelonephritis is present, the patient should at once be put to bed, and a permanent catheter inserted. This should be, preferably, a soft rubber catheter, and should be, approximately, of the largest size that the meatus will permit to pass. It should not, however, be below 18 French. If the meatus will not allow the passage of an instrument of this calibre, it should be enlarged sufficiently to permit such an instrument to pass. There are a number of appliances which enable us to fasten the catheter in place, but a very simple one can be made with a safety pin, which penetrates the upper wall of the catheter, just beyond the meatus, to which silk, or strong linen threads are attached, these threads passing back, along the sides of the penis, and being kept taut and in place by a zinc oxide plaster strip, encircling the organ, but making no pressure. Such a permanent catheter, which must, of course, be inserted under the strictest aseptic precautions, should be removed daily and resterilized, by boiling, care being taken, at such times, to thoroughly irrigate the urethra and bladder in the manner before mentioned. It is a surprising thing to note how well the permanent catheter is tolerated by the majority of patients, and how quickly the complications for the treatment of which it is used respond thereto.

A not infrequent complication, where the patients catheterize themselves, or where the catheter is carelessly used, is epididymitis, or orchitis, or a combination of both. Usually it is not severe in character, although it may go on to suppuration. Under such conditions the patient should at once be put to bed, and, where the vesical symptoms are at all pronounced, the permanent catheter be inserted, in order to avoid the danger of frequent catheterization. All patients suffering with prostatic hypertrophy should drink freely of water, and many are benefited, particularly in the presence of cystitis, by Wildungen, or some of the similar waters.

When the patient's local condition is such that it does not respond readily any more to palliative treatment, and when no complicating conditions exist which forbid operative procedure, then radical measures must be employed. I do not believe that any patient's chances of recovery are impaired by palliative treatment, so long as the symptoms respond thereto; but I do not believe that one is justified in delaying radical operation where palliative treatment fails to achieve tangible results. While our aim as physicians must be to save our patients any unnecessary risk, we should recognize the fact that when the risk must be taken, there must be no unnecessary delay.

# ATTEMPTS TO REPAIR THE EFFECTS OF GREAT DESTRUCTION OF THE LIDS AND ORBITAL TISSUES CAUSED BY DISEASE OF THE ANTRUM.\*

By BURTON CHANCE, M. D.,  
Philadelphia.

The early history of this case, without which I could not have understood the cause of the awful conditions present when I first saw the patient, was given me by Dr. Beaman Douglass, of New York, and I now express my obligation to him for the information. The young woman had had a disease of the left antrum which had been caused probably by infection from a decayed molar tooth. The disease spread into the orbit after necrosis of the roof of the antrum. Orbital cellulitis followed, and later the eyelids became the seat of numerous abscesses. In a short time panophthalmitis occurred, and the eyeball had to be removed.

Dr. Douglass opened the antrum, which he found filled with infected granulation tissue. After thoroughly curetting this cavity he removed all of the necrotic bone, thus enlarging the opening into the orbit and establishing communication into the middle nasal meatus. The abscesses in the lids were opened and drained; other incisions were made to ascertain the state of the frontal and the ethmoidal sinuses. Here all the osseous tissues and spaces were healthy, and they were left undisturbed. Drainage tubes were placed in the opening between the orbit and the antrum, and these cavities were drained. Further treatment consisted in frequent cleansing and of the removal of redundant granulations. Dr. Douglass viewed this as one of the most interesting accessory sinus cases he had ever had, and he could hardly believe it possible for so great destruction to follow disease of the antrum.

The patient was a well-developed young woman. Over her left orbit was a large, thick black silk patch. On the cheek were several scars, one as though it were the scar of an incision, others as though it were excoriations, while along the superior orbital ridge were those from the exploratory incisions near the frontal and ethmoidal regions. The globe had been removed. The orbit was partially filled in by the bones adjacent to the maxillary pyramid. There was sufficient movement of the mass to justify the assumption that the ocular muscles had not been entirely destroyed. The upper lid, which was greatly distorted and stretched, was firmly adherent to the roof of the orbit. The inner third was puckered, and from the edge projected distorted skin. The lower lid had become firmly adherent to the orbital border. Here, surrounded by numerous radiating cicatricial bands, was a sinus leading from the orbit into the cheek and discharging on the cheek. The antrum was filled with granulation tissue, and the sinus was the seat of a small opening into the nasal cavity, and through which air could be blown out of the mouth. Fetid pus exuded from all these sinuous tracts.

The patient was very grateful. The only reason brought me to try to repair the upper eyelid was the hope that some prosthetic effect might be obtained by repairs to the orbit.

My first efforts were directed towards thorough cleansing of the cavities and the maintenance of drainage. The patient was wearing the patch which created a broad oven out of the orbital cavity and excited irritation of the surrounding skin.

restorative plastic operations, but even these were experienced as he the conditions were formidable and discouraging. The patient was entirely willing to submit to a series of operations without demanding my assurance of definite results. Accordingly she was admitted to the Germantown Hospital. After complete ether anesthesia I examined the orbital cavity in a way in which I could not have done it before. The lids were not united to the floor and to the roof of the orbit throughout their whole extent, but only here and there, the contiguity being interrupted by sinuous tracts which led to the deeper conjunctival sacs, where the mucous membranes were apparently preserved. The tarsal cartilages had been damaged by the suppurative processes. Bands of adhesions had formed between the lid margins and the orbital tissues which had retracted so greatly as to draw the lids far into the orbit. The inner third of the lower tarsal border had been destroyed. There were no signs of the lacrimal punctum or caruncle, nor of the sac of the inner fornx. The apex of the orbit was filled with the remains of the extraocular tissues. The sinus opening into the cheek communicated with several pockets containing putrid secretion.

After this survey I determined on a plan providing for a series of operations, some of which had been suggested by my friend Dr. Roberts. In the performance of the operations I was given much help by Dr. Charles Plank, the senior resident of the hospital, and here I wish to express my obligation to him for his patient care of the woman while she remained in the wards.

The first operation consisted in carefully dissecting the lids free from all adhering bands so that they hung over the orbit like loose flaps. Greater mobility of the lids was gained by an external canthotomy, and more space was obtained in the orbit by the severance of the larger distorting bands. As the lacrimal punctum could not be found, a stout conical probe was forcibly pushed through the soft tissues and entered into the duct. A thick lead style was inserted afterwards and passed down into the floor of the meatus and left in the duct, the upper end of it bent and embedded in the soft tissues of the orbit. The sinus into the cheek was not disturbed, but was left to drain the excessive secretions from the orbit.

A piece of sheet lead was fashioned and placed over the base of the orbit. This plate fitted into the angles corresponding to the retrotarsal space. Then, with the hope of effecting an anchyloblepharon, the lids were drawn over the convex surface of the plate, and their edges freshened. They were united by interrupted sutures.

The reaction following these procedures was intense; great edema of the lids persisted and the patient complained greatly of pain. In a week, because the sutures broke loose, the lead plate was withdrawn and a ball of hard paraffin was inserted in the cavity. Simple dressings were used and firm pressure applied. The sinus in the lid was swabbed with pure carbolic acid. After a week the pus had ceased to flow, the discharge had lessened, and it was noticed that the orbital mass could be moved more freely than was the case before the operation. The skin on the cheek was beginning to heal. In general terms a distinct benefit had been gained.

At stake of going supernumerary and to a few days the patient asked to be allowed to go home. That was the way she applied for treatment of the antrum to Dr. Carl L. Felt to whom I had recommended her.

When the parts were examined three weeks later much of the raw surface was found to be healed, and there was considerable retraction and distention of the tissues. Again the adhesions were broken and another lead disk was inserted over which the eyelids were united by silk and catgut sutures. Only slight reaction ensued and in ten days the results were more satisfactory than at the earlier operation. The eyelids were not united in their entire extent, yet they covered the orbital outlet. The fistulous tract into the cheek was closed by a small flap of skin sutured to the inferior orbital margin.

The patient received a luetic infection two or three years previously. Because of this, and because of the great value I believe mercury has as an anti-plastic, applications of mercurial ointment were made to the raw surface. The result was a

repair the distorted upper lid. Adhesions were broken, and exuberant granulations were removed. An incision was made in the lid above the point in the border where the distorted portion joined the natural. Again a lead style was inserted into the lacrimal duct. An ordinary glass shell was placed in the orbit and the lids were sewed together over it. Iced bichloride compresses were applied without interruption for three days. But little swelling or discharge followed, though the parts were tender and the patient complained of considerable pain.

At the end of a week the sutures were removed. There was firm union in the inner third, but less firm in the outer. In spite of the great mutilation that had taken place in the tarsal cartilages there was a noticeable, indeed even marked, movement of the two lid flaps. The lower flap was composed of the cutaneous and subcutaneous tissues of the facial region, together with the inner fibers of the orbicular muscle. The upper flap included similar tissues in the inner portion and contained a very much distorted tarsal cartilage in the outer.

At the end of another week the tissues conformed quite regularly over the temporary glass shell. The tarsal border had become more extensive; the canthoplastics had increased the general dimensions of the fissures, and the dense cicatrization in the tissues at the lower border had favored the eversion of the lower flap.

One month later a gold sphere was inserted beneath the muscular cone of the orbital mass. The metal conformer excited pain and induced considerable discharge, so that by the end of a week it had to be removed, at which time the sutures were withdrawn.

The patient was discharged from the hospital on November 15, 1904. After another month of irregular attention, she disappeared and has not presented herself again. When I saw her the last time the lower lid had become adherent to the orbital mass, but the sphere had so molded it that the upper lid had become decidedly convex and overhung the lower lid. There was at that time a resemblance to a tarsal border along the upper lid. The cavity was drained perfectly by the nasal duct, and the antral discharge had ceased.

Mr. Joseph Ferguson contrived a pair of spectacles containing large periscopic lenses, the left having ground surfaces, which greatly obscured the disfigurement; but the lady discarded them for the black patch of earlier days.

235 SOUTH THIRTEENTH STREET.

## DISLOCATION OF THE NECK WITH RECOVERY.\*

By LUCIEN LOFTON, A. B., Ph. D., M. D.,  
Emporia-Belfield, Va.,

Coroner and Health Officer to Greensville County, Va.

Traumatic injuries of the cervical vertebrae and spinal cord are declared by many able surgeons as being invariably grave; a majority of such conditions are said to be usually followed by an early death or permanently bad results. A few cases, however, are on record where a satisfactory recovery has been observed.

Boswell mentions a man of sixty whose fourth cervical vertebra was subluxated and who recovered within two weeks. Lazzaretto reports a case of a seaman whose atlas was dislocated and who made an uneventful, though somewhat tedious, recovery. Vanderpool describes a fracture of the odontoid process, but death ensued about six months after injury. Ashhurst, Phillips, the elder Cline, Willard Parker, Bayard, and Stephen Smith have reported partial and complete recoveries after fracture of the atlas and axis. Doyle in 1896 attended a woman patient with a dislocated neck who made a fairly good recovery within seven months, and who was enabled to follow her daily vocations around her farm.

Ashhurst especially refers to the condition of dislocated neck and says the mortality is always high. His experience with three hundred and ninety-four cases no doubt justifies this conclusion. Barney Baldwin, the erstwhile Louisville and Nashville railroad switchman, who exhibited himself throughout the country several years ago, suffered from a dislocation of the neck in the cervical portion of the spinal column. It is not generally known that the Earl of Minto, Viceroy of India, is one of the few notables who ever survived a broken neck. This accident befell the viceroy thirty-one years ago and was reported by the distinguished English surgeon, Sir James Paget. This famous physician declared after his patient recovered "that in the whole of his experience it was the only instance he knew of the vertebrae going back into the place after being stretched." A few other interesting examples of this character could be enumerated which have appeared in the medical journals of which every surgeon has easy access.

The case of dislocated neck the writer desires to report is that of William N., white, age twenty, of Emporia, who at the time of accident was employed as a daily laborer on the Tidewater Railroad.

The writer was summoned at 1 p. m. to attend this man in July, 1906, at Rural Bower, a distance of fourteen miles from Emporia. I reached the injured boy about three hours after the accident had taken place. Upon examining the condition of the patient complete motor and sensory nerve action were found to be absent from the chin downward, barring a slight movement from the right index finger, which could be feebly flexed.

Before proceeding further I desire to briefly describe the origin of the dislocation. The young man while assisting in adjusting an "idler" chain beneath a steam shovel was caught around the neck by this powerful linked rope and drawn up against the floor of the machine and securely held there for several seconds. The engineman above, mistaking the signal, started the machinery below, and thus was the unfortunate youth drawn near his doom. The left side of the boy's head was pressed directly against the under surface of the steam shovel, and when released the body fell limp and, to all eye witnesses, apparently lifeless to the ground. A number of intelligent observers, after removing the body, pronounced life extinct, but fortunately, within a few seconds signs of resuscitation were observed. When the young man awoke, as it were, he asked for water, which he could not then swallow after repeated attempts during a period of an hour.

At the time I reached the young man his condition was improved to such an extent that, upon offering a liquid, he could with great difficulty use some of the muscles of deglutition. Practically no pain was complained of other than that his "neck was sore." The respiration was fourteen to the minute, and the heart showed a count of fifty-eight beats. The paralysis mentioned was absolute; likewise necessarily complete loss of function of the bladder and bowels. The patient talked intelligently, would whistle, expectorate, protrude the tongue, and rendered any facial contortion requested of him.

A more minute examination of the boy's injury revealed the fact that his neck muscles and ligaments had stretched approximately one and one-half inches beyond normal conditions. Upon manipulation the ventral arch of the atlas was found resting upon the odontoid process of the axis. The man had been placed upon a flat ground surface where, in the following manner, I reduced the luxation. Summoning four men, I directed two to grasp a lower extremity, that the patient might be held evenly in proper position. The other two assistants rested their hands upon the thorax to steady the trunk. Then firmly grasping the occiput with my right hand, I placed the left under and around the chin, when by lifting the head backward, upward, and forward upon the chest the atlas was replaced to its normal position. Each step of the manipulation was deliberately and slowly accomplished, owing to the fact I did not know to what extent trauma had entered into the

\*Through members were welcomed, Medical Association of Virginia and North Carolina, at Norfolk, Va., December, 1907.

proposition. I felt reasonably certain that the cord or its meninges were in a measure lacerated. During the reduction of the dislocation no anæsthetic was used for fear of its painful results, and much pain was complained of by my patient, especially in the region of the throat, and as expressed by him "felt as if about to choke." No immediate sensory or motor improvement was noted upon reducing the displacement other than a desire to micturate.

With one inch surgeon's adhesive strip, I firmly fixed the neck and head in as normal position as possible. The man now requested that his bladder be relieved, which was done three times within three hours, voiding each time approximately from three to four gills, of deep amber color. In an improvised ambulance I moved the man to Emporia over one of the roughest public highways in the State. Upon arrival at destination the pulse was 76 and respiration 19. At no time did he become delirious after originally regaining consciousness. The patient arrived home in fairly good condition, about eleven hours after being hurt. He was placed in bed, with the head of bed elevated about eight inches. An additional bandaging of the neck and head reinforcing the adhesive strip was thought necessary. After a teaspoonful dose of a narcotic the boy fell into a restless sleep which lasted for three hours, at which time the narcotic was repeated and brought on the desired effect. The pulse and respiration continued practically normal for three weeks. At no time did the temperature rise above 99.6 from the traumatic condition.

On the fourth day the paralysis began to clear in the left lower extremity and in the right forearm. On the seventh day the right foot began to be used, provided the boy would direct and concentrate his mind upon this spot. Then followed gradually the use of the muscles of deglutition, the erector spinal muscles and the entire general muscular arrangement, including the bladder and bowels.

The patient did not at any time suffer any mental disturbance. He did not attempt to assume other than the dorsal decubital position for ten days, but after this time, when I began massage, hot sponging, and the faradic current from twice to five times daily, he would change his position with only partial assistance.

On the fifteenth day the boy contracted measles, which ran the usual course. The young man had tonics and alteratives for two months along with the treatment as described. A light but nutritious diet was given during his illness and confinement to bed, and was increased to a full diet upon leaving it.

On the twenty-ninth day after the injury the boy was able to sit up and walk a few steps, but it was sixty-three days before he ventured out of his chamber. The massage and electrical stimulation was conscientiously applied for five and a half months, with the result that the only evidence of the original injury is a partial atrophy of the deltoid muscles covering the shelf of the left shoulder. I have purposely avoided going into the minute of the nerve structure herein involved, for I feel assured the distribution is generally known and any attempt upon my part to describe the neural complications would prove unprofitable to the reader.

#### THE PRINCIPLES OF THE CLIMATIC TREATMENT OF CHILDREN.\*

By F. L. WACHENHEIM, M. D.,  
New York.

Climatic treatment is often recommended for various subacute and chronic ailments of infancy and childhood, but few authors have cared to lay down the general principles which must be our guide in ordering a change of air for our young patients. As a rule, our recommendations have been largely empirical, with a resulting uncertainty as to what can actually be accomplished in applying climatic treatment to this or that group of cases. I may, therefore, be pardoned for taking up the time allotted to me with a brief outline of the underlying

principles of climatotherapy, particularly as applicable to early life.

The three most important climatic elements which we have to consider are the temperature, the various phases of atmospheric moisture, and the pressure of the air, the last chiefly as modified by the elevation above sea level. We may commence with a discussion of the general therapeutical principles applicable to all of these, and then take them up severally.

We have two methods of applying physical therapeutics of all kinds, including climate; one consists in training or developing the diseased body or organ by exercise, the other in aiding the restorative powers of nature through reduced functional activity, or what we may briefly call, in the German fashion, a rest cure. The former is indicated when the body or any of its organs suffers from imperfect development or functionate poorly from disuse. A course of training, likely to be ineffectual or even dangerous in advanced life, is almost certain to yield excellent results in childhood, if applied with judgment to patients affected with such diseases as, for example, rickets or scrofulosis; it is very generally agreed that removal to a stimulating climate is of the greatest benefit to these cases. When, however, the body or any of its parts is already overstrained and for that reason unable to cope with the work that normally falls to it, a rest cure is called for. Here, likewise, the indication is more urgent in childhood than later, for in the young subject overwork entails far more danger of permanent impairment than in the adult, and, on the other hand, there is a much better chance of complete, or at least satisfactory, restitution if appropriate measures of resting be applied, a sedative climate being one of the very best of these. Climatic rest cures are especially indicated in such affections as nephritis and uncompensated cardiac lesions.

In applying the diversities of temperature in accordance with the outline just given, our first object must be to ascertain that indifferent temperature which feels neither warm nor cool, and is therefore most restful. In the normal adult the indifferent temperature stands at about 75° F. in summer clothing and 65° F. in heavy winter garments, but is reduced about ten degrees by such moderate exercise as walking. In children the indifferent temperature ranges higher, only a few degrees toward puberty, five or more in early childhood, varying considerably according to individual robustness, rising rather rapidly to near the body temperature in earliest infancy. Thus the indifferent or restful temperature varies greatly according to age; the average July afternoon temperature at, for example, Atlantic City, namely, 78° F., is decidedly bracing for young infants, indifferent for children who are just able to run about, too warm for older and very active children. It must be remembered, in this connection, that temperatures above the indifferent point are not at all sedative, but involve a continuous stimulation that is most harmful if prolonged, leading to exhaustion of the type called enervation; in physical therapeutics in general, the belief in the sedative effect of warmth is a common error.

\*Read before the Section in Pediatrics of the New York Academy of Medicine, February 13, 1908.

It is evident, from what I have said, that we have within our reach some very delicate gradations in applying the climatic rest cure, if we balance carefully the factors of temperature, age, and exercise. When, on the other hand, we desire to employ measures of climatic training, the matter is extremely simple, as we need only recommend a climate averaging ten degrees or so below the indifferent point for subjects who should move about freely, and a somewhat milder region for children under three or four years of age, or such as suffer from a disabling disease of the lower extremities like chronic rheumatism, tuberculosis, or a traumatism.

The practitioner unfamiliar with climatic details will, of course, be obliged to look up climatic tables, besides sizing up his patients carefully. It is also well for the pædiatrician to remember that young children stand severe cold badly, so that a transfer to the very frigid winter climate of the Adirondacks, for example, is neither necessary nor even advisable before the age of ten or twelve years. Furthermore, it is evident that temperatures above the indifferent point are not to be employed under any circumstances; the stimulation of cold can readily be checked, if undesirable at any time, by resorting to extra clothing and artificial heat, but the effects of heat cannot be counteracted by any known method. In applying any course of physical training, the chief danger is from excess or undue prolongation of our treatment, with the resultant exhaustion which is invariably injurious.

As to the atmospheric moisture, I can speak more briefly. Rain is useful in moderation, especially if it falls in brief showers to lay the dust; a permanent winter snow sheet is of inestimable value for the same reason, but the alternation of frost and thaw, rain and snow, met with in our Eastern States from Massachusetts to New Jersey in ordinary winters, is objectionable as causing sloppiness underfoot and interfering with outdoor exercise. The proportion of aqueous vapor in the air, known as the relative humidity, is important in that it checks the evaporation of body moisture and consequent reduction of body temperature in proportion to its own percentage. A low relative humidity is extremely valuable in lowering the sensible temperature, or, what amounts to the same thing, raising the indifferent temperature. Thus the sensible temperature in summer is eight degrees lower at Denver than at Atlantic City, though the dry thermometer registers the same. The latter locality is somewhat enervating for older and fairly robust children, whereas the former is bracing, on the whole, in spite of pretty high afternoon temperatures. At temperatures below the indifferent point the relative humidity has no practical importance, not being physiologically perceptible; thus our northeastern hills are popularly credited with a dry winter, whereas observations show that it is damper there than on the coast; the truth of the matter is that we cannot feel any difference whatever. Clinically, the relative humidity at moderately high temperatures is important for such cases as call for tree transpiration, where we desire to relieve the kidneys by causing diaphoresis; here a warm and moist climate is indicated as being the

best mild diaphoretic known. Such localities as the middle Atlantic coast in summer, the south Atlantic coast in winter, and the southwest California coast at all seasons are sure to be of value in chronic nephritis or albuminuria.

As to great altitudes, we know that they cause a hypertrophy of the red blood cells in proportion to the elevation, and, as a necessary consequence, a general stimulation to metabolism; they are therefore admirable as a general tonic in torpid states, but contraindicated in severe organic disease, where rest is indicated. Elevations below 1,000 feet may be disregarded; those up to 3,000 feet are most generally useful where a moderate toning up is desired; the higher levels are only to be resorted to where a course of physical training is distinctly called for, as in older children who have become enervated from excessive warmth or lack of exercise. The anæmias of young subjects do best at the moderate elevations of our Eastern mountains, and the same is true of the victims of general malnutrition, rickets, scrofulosis, and chronic tuberculosis. Greatly debilitated children are indeed benefited most by elevations of 500 to 1,500 feet, and in their case some such alternation as New York or New England in summer and the Carolinas in winter will be found to produce the best results.

I regret that the time allotted has been sufficient only for a broad outline of a few generalities; on the other hand, I feel that a clear comprehension of the fundamental principles of the climatic treatment of children is calling for special consideration at the present time.

#### A RETROSPECT IN PHTHISIO THERAPY.

*Showing Some Curious Ideas as to the Treatment and the Development of the Modern Method.*

BY HENRY FARNUM STOLL, M. D.,  
Hartford, Conn.

Since centuries tuberculosis has been recognized as the greatest scourge the human race has ever known. Described with great accuracy by the fathers of medicine, Hippocrates, Galen, Celsus, and others, each generation has brought forth physicians who have assiduously devoted themselves to conquering this disease, yet it is only within recent years that its cure has been thoroughly established. In ignorance of the ætiology, knowing but little of its pathology, yet eager to stay its ravages, it is not strange that many "cures" were announced from time to time which proved unworthy of the name. And it is the memory of these bitter disappointments that is responsible for the iconoclasm with which each new announcement in phthisiotherapy is received.

Many centuries ago the contagiousness of tuberculosis was attested to by Aristotle and Isokrates, and later Avicenna, the father of Arabian medicine, recognized its infectiousness. While its contagiousness was appreciated by "all the inhabitants over the levant" (1) as early as the eighteenth century, the Italians were the chief promulgators of this doctrine. It is said (2) that Valsalva, who had a consumptive tendency, would leave the autopsy whenever the lungs of a person dying from consumption were dis-

sected. In 1757 Cocchi furnished the Florentine authorities with certain directions to prevent its spread, which are surprisingly like the circulars issued by our boards of health to-day. Consumptives were urged to avoid living in small, stuffy rooms, choosing rather large, airy ones exposed to the sun's rays. The edict states (3) that "the sick should only spit into vessels of glass or dried porcelain, which should be frequently and thoroughly cleansed," and physicians who failed to report their cases were fined 300 ducats for the first offense and exiled for ten years for the second.

In the north of Europe, however, where superstition was rampant, where monarchs were "touching" for scrofula, where all sickness was either an evidence of divine displeasure or of evil spirits, this infectious theory was slow of adoption. Dr. Heberden considered his experience as hardly sufficient to justify an opinion, yet he had seen "too much appearance of it to be sure that it is not so." The things which we recognize as secondary or contributing causes—excesses, overwork, exposure, overcrowding—were considered by some as the primary or real causes. Then as now the dress of the gentler sex was severely criticised, one writer remarking that "the scant, light, and flimsy attire of our modish females very much increase the liability of the complaint," while another stated that "the nakedness of women is the clothing of the physician."

Laennec, the father of auscultation, observed the very high mortality from consumption in the religious orders of women. This Laennec accounted for by the depressing influence of the "ascetic spirit" which regulated their lives. During ten years he witnessed two or three renewals of the society by admission of new members to replace the loss of old ones, and that "the only ones who withstood its depressing influence were the superior, the gatekeeper, and the sisters who had charge of the kitchen, the garden, and the infirmary. These latter had occasionally to visit the city" (4). Could a clearer case of house infection and a more eloquent plea for the outdoor life be imagined? It would seem that Laennec would have been persuaded of the infectiousness of the disease from this example alone, but as Walsh truly remarks, "Even genius makes but one step into the unknown" (5).

Some idea of what the treatment was two hundred years ago is obtained from Robinson's *New Method of Treating Consumption*, published in 1720. It will be recalled that at that time the scientists were divided into two schools, the iatrophysicists and the iatrochemists, and to the former belonged Robinson. He tells us that this "new method" is based upon an endeavor "to account for all the phenomena's attending consumption, from the laws of attraction, motion, and division. These are the three grand principles on which the several springs of the constitution turn, and to which all the symptoms of health and disease are referable" (6). He gives a dozen propositions, which contain frequent reference to "solids," "fluids," "elastic spring," "balance of Nature," "tenacity of fluids," etc. It is explained that these propositions are founded upon "a kind of mathematical reasoning without numbers." He refused to accept the teaching of those who asserted that the disease was due to "acid, sharp corroding

humors; putrid, sharp blood; sharp saline, volatile lymph; worms or animalculæ's fretting or gnawing the vessels of the stomach, lungs, liver, etc." (7). It was much simpler to consider it occasioned by "obstructions and tumors in the viscera" which were caused by "a collection of juices" as the results of a "depression of the solids" (8). The symptoms were directly referable to "the force of the heart not decaying in a simple proportion to the resistance of the other parts" (9). Notwithstanding this remarkable theory as to the aetiology of consumption, Dr. Robinson appears to have been a rather close observer and a man possessed with a good bit of common sense. He speaks of the poor digestive powers of those who are "inclined to consumption," and gives some excellent advice concerning the "cough that paves the way to decay." "This, methinks, should make all people, but especially those of weakly constitution, exceedingly careful, that they suffer not a cough to continue; for it is a dangerous enemy to play with, and several—I speak it of my knowledge—have greatly endangered their lives by neglecting in the beginning an indisposition of such seeming slight consequence" (10). He considered "a light, thin, clear air, not too sharp," an easily digested diet, and proper exercise, with "a command of the passions," as the essentials in the treatment. Bleeding was not favored, but "gentle vomits" were advised and "cheerful and innocent recreations" were thought highly of. This treatment was augmented by "a few of the most choice and generous medicines." He prized the juice of turnips very greatly after seeing improvement follow its use in a certain case where "whole pailfuls of ass's milk and vipers' broth" have been unavailing. As a "constant drink" he recommended a preparation made from pure milk and egg albumen. Dr. Robinson shared the popular belief that the night air was harmful. In fact, he thought that night was "more than a privation of light, for it consists of particles (whatever they may be) that are capable of abating the air's spring" (11), and in substantiation of this he quotes, "and there was darkness in all the land of Egypt, even darkness that might be felt." Exercise he recognized as very important, but just why it was necessary he frankly states is "above his philosophy to determine," yet he thought that its necessity occurred coincident with the fall of man, "for they that will not labor, that is, exercise, seldom have an appetite to eat, or at least a true relish of the meats and drinks they take for the support of nature" (12).

Some rather startling therapeutic measures were advocated by one John Wesley, M. A. (13), who in the middle of the eighteenth century wrote a book which "was intended more especially to aid the clergy in meeting the frequent demands of their flock in cases where physicians were not easily accessible. The seeming ease with which he cured his patients with the simplest of remedies must have won for him great popularity:

One in a deep consumption was advised to drink nothing but water, and to eat nothing but continental's, such as salt or sugar. In three months, then, he was perfectly well. Or, take a quart of ale or a pint of light, pure or small beer. Boil in this three or four ounces of bay leaves, and two or three pieces of licopod. Drink over night half, the rest in the morning. Do this if needed not two months daily. This has cured a desperate

case. Tried. Or, take a cowheel from the tripe house ready dressed, two quarts of new milk, two ounces of isinglass, a quarter of a pound of sugar candy, and a trace of ginger. Put all these in a pot, and set them in an oven after the bread is drawn. Let it continue there till the oven is near cold, and let the patient live on this. I have known this to cure a deep consumption more than once. Or, every morning cut up a little turf of fresh earth, and lying down, breathe into the hole for a quarter of an hour. Tried. Mr. Masters, of Eversham, was so far gone that he could not stand alone. I advised him to lose six ounces of blood each day for a fortnight, if he lived so long, and then every other day, for the same time. In three months he was well.

The popular treatment at the beginning of the nineteenth century was the so called "antiphlogistic," which, as the name signifies, was directed against the inflammation rather than its cause. To this end emetics and cathartics were freely employed, bleeding was performed, and the diet was meagre. The introduction of bleeding in the treatment of this disease is attributed to Dr. Dover, whose name has been perpetuated by the well known "Dover's powder." He recommended that it be performed at first daily and in small amounts; after the second week it was to be done every second or third day for a considerable period of time. "Cases are on record in which before the disease proved fatal, blood letting had been performed upward of fifty times" (14).

The popularity of emetics is attested to by Richter (15), who tells of a woman aged forty years who took 600 emetics in ten years! And Dr. Witt, physician to the Infirmary of Bedford, said, concerning the treatment of incipient cases, "When I have been successful I have in my own mind attributed these successes mainly to the unsparing and persevering use of emetics" (16). "Could phthisis ever be cured," said Dr. Parr, "it would be by the joint action of emetics and blisters" (17). These latter were shifted hither and thither over the chest with the idea of "preventing the tubercles from proceeding to suppuration." Dr. Simmons, an Englishman, extolled the *baño de tierra*, or earth bath. His patients would spend considerable time in pits which had been freshly dug in the earth. The efficacy was supposed to be due to "the antiseptic powers of the exhalations from the earth," which were thought to be absorbed by the body.

In 1787 an extraordinary plan of treatment was published by Salvadori (18), who claimed to have evolved the treatment by combining the methods of Hippocrates, Bennett, and Sydenham. Discarding medicine and all exactness of regimen, he directed his patients to climb, in the morning, some high eminence as quickly as possible, till out of breath and bathed in sweat. He then was to place himself near a large fire in order to increase the perspiration. Afterward the linen was changed and the patient gradually withdrew from the fire to partake freely of salted meat and wine.

The demonstration of oxygen by Priestley about the middle of the eighteenth century was followed by an attempt to cure disease by this "vital air." Other gases were discovered, and these two were tried in the treatment of disease. Pearson, of Birmingham, administered ether for the relief of consumption in 1795 (19). Thomas Beddoes advocated the inhalation of oxygen, hydrogen, and other gas in the treatment of consumption, and in the latter part of the eighteenth century he founded a medical pneu-

matic institution at Bristol for the treatment of this disease (20).

While the treatment of tuberculosis was not advanced by this institution, it was here that Humphry Davy began and carried on his notable researches on nitrous oxide, and it was here that he inhaled that gas while suffering from a toothache, and discovered, to his great delight, that it relieved the pain. This led to his writing in 1800: "As nitrous oxide in its extensive operation seems capable of destroying physical pain, it may be used with advantage during surgical operations in which no great effusion of blood takes place" (21).

This same Thomas Beddoes was loud in his praise of digitalis as a cure for consumption. "I daily see many patients in pulmonary consumption," he says. "advancing toward recovery with so firm a face that I hope consumption will henceforward as regularly be cured by the foxglove as ague by the peruvian bark" (22). This worthy gentleman advocated one of the most unusual of the numerous methods of treatment. He believed that a steady warmth diminished one's chances of contracting the disease, and, if already its victim, would bring about a cure. Difficulty seems to have been experienced in obtaining what he describes as "an atmosphere permanently modified, of a regular temperature, and at all times likely to improve the conditions of pulmonary ulcers." After trying many plans he tells us that "residence in a cow house (as first recommended by Bergins) (23) seemed by far the simplest, safest, and least disagreeable." Strange as it may seem, the public did not take altogether kindly to the idea, for the doctor adds: "Nor is it without extreme regret that I now look back upon the number of instances in which my recommendations failed. Not infrequently did I forfeit the good opinion of my patients" (24).

The persuasion of the patient appears to have been but half the battle, judging from the account of the trials of a certain Irish lady. This estimable person "went to considerable expense in fitting up a cow apartment. But a mob of females who could by no means bring themselves to fancy the scheme, having unhappily got intelligence of the time when the cows were to be driven through a certain passage, assembled at its mouth and scared the animals so much that their passionate owner, notwithstanding the extravagant price for which he had bargained, refused the patient their use on any terms." As the cows' horns were apt to be noisy at night, young cows were desirable, and the use of halters rather than chains was advocated for a like reason. A patient of a Dr. Saiffert, who employed this same treatment in France, describes her experiences in a letter to a friend as follows: "My bed was placed upon planks about one foot from the ground. These planks were purposely ill joined, that the vapors might penetrate, and it was so strong that everything white which was brought in became reddish in a very short time." That she was a person of distinction is evinced by a reference she makes to a visit from the Duchess of Orleans, and by her stating that her physician forbade her playing on the harp because it caused shortness of breath (25).

In one case, where, we may presume, Dr. Beddoes's eloquence was not sufficient to carry out the

cow house treatment, he tells us that "double doors and double windows were added to a bedroom. The fireplace was bricked up round the flue of a cast iron stove for giving out heated air." And, almost incredulously, we read that the poor patient lived nearly a year and a half. Dr. Michael Peter describes such a room as a place "hideously fetid . . . where both air and hope are alike forbidden to enter" (26). The belief in the baneful effect of cold air was very generally shared by the physicians of those days. Andrew Duncan, physician extraordinary to the King, said that the consumptive should "confine himself to the house during the coldest months in the winter and never allow the atmosphere of his room to be under 48° F.," and another, writer explains that "tubercles are evidently induced and accelerated in winter and retarded in summer."

The treatment of Dr. Francis H. Ramadge (28) is of interest in connection with the inhalation mask recently devised by Kohn (27), which, by obstructing inspiration, increases the negative pressure within the thorax, causing air hyperæmia. Ramadge, who was a pupil of Laennec, practised medicine during the early part of the eighteenth century in England. One of his patients, who was a consumptive, was attacked with a swelling above the sternum and so situated that it made a great deal of pressure on the trachea, "almost causing suffocation." At the end of some weeks a marked improvement was apparent in the pulmonic condition, and by the time the swelling subsided, the consumptive appeared to be cured. In another case he placed a silver band about the patient's neck, to which was fastened an ivory ball which pressed firmly against the trachea. This case also showed improvement, and, acting on this principle, he had constructed an inhalation tube four feet long, whose calibre was many times smaller than that of the windpipe. Later he constructed a tube with a valve, so that expiration took place through a much smaller opening than inspiration. Fitch (29) in this country was an ardent advocate of this tube.

The prognosis of this malady at the beginning of the nineteenth century was distinctly bad. Dr. Young, of St. George's Hospital, saying: "It is probable that without assistance not one case in a thousand of the disease would recover, and, with the utmost power of art, perhaps not more than one in a hundred will be found curable" (30). "Fellow Laennec," said Dr. Davis: "I can give you no better guide, but do not go straight to the work with him and attempt to cure consumption. Stop short and be warned by me—for I have enjoyed a liberal allowance of failure—that it cannot be cured" (31). Less than a hundred years ago an eminent divine told Fitch that it was blasphemous to assert that the disease was curable, "for God Himself had made it incurable" (32).

There was, however, a smaller class of physicians who maintained that the malady was amenable to treatment, and, discarding the popular antiphlogistic regime, they strove to support the patient's strength by tonic, fresh air, and a liberal amount of food. "The stimulating plan of treatment," said Sir James Clark, consulting physician to the king and queen of the Belgians, and physician to the Duchess of Kent and the Princess Victoria "I do not consider

deserving of mention" (33). One of the pioneers to advocate this method was Benjamin Rush, who practised in and about Philadelphia during the latter part of the eighteenth and the beginning of the nineteenth centuries. Except for his use of the lancet, he treated his patients along much the same lines that we employ to-day (34). "It is vain," he asserted, "to depend upon internal or external medicines. The whole system must be strengthened or we do nothing" (35). He was a firm believer in exercise, but he urged that it be not prolonged to the point of fatigue. He sums up the treatment in this concise fashion: "If it were possible to graduate the tone of the system by a scale, I would add that, to cure consumption, the system should be raised to the highest point of the scale" (36).

The first physician to advocate sleeping out—which we are apt to fancy is quite a "new idea"—appears to have been Nicholas Way, of Quaker origin, who was born about 1750 and graduated from the University of Pennsylvania in 1771. He practised skilfully in Wilmington, Del., and took an active part in the yellow fever epidemic of 1793. After his removal to Philadelphia in 1796 he was appointed president of the mint. Concerning him Rush says: "Dr. Way, of Wilmington, informed me that a certain Abner Cloud, who was reduced so low by a pulmonary consumption as to be beyond all relief from medicine, was so much relieved by sleeping in the open air, and the usual toils of building a hut and improving a farm, in the unsettled parts of a new country in Pennsylvania, that he thought him in a fair way to perfect recovery" (37).

In England, Andrew Stewart seems to have been one of the first to see the fallacies in the popular antiphlogistic treatment, and interwoven with his practice is a very pretty romance. In 1796 he received his license to preach from the University of Edinburgh, and six years later his medical degree from the same institution. It was while attending the lecture of an eminent physician who was advocating the antiphlogistic treatment that he first questioned its validity. "Why," he reasoned, "should an entirely different method be adopted for treating ulcers of the lungs than for ulcers on the surface of the body?" His first charge was at East Lothian, where he established a reputation for curing consumption. In 1804 he was presented to the parish of Bolton, Haddingtonshire, by Lord Bantyre. Now, it so happened that his lordship had a daughter, Margaret Stuart by name, who was a consumptive, and it is possible that he had heard of this young medical preacher who cured tuberculosis, and desired that she be under his care. Be that as it may, we know that she became a patient of Dr. Stewart's, and the good doctor cured her. So grateful was she that she consented to become his wife, and "they lived happily for many years afterward." The only description we have of his method of treatment is contained in a letter (38) written by one of his patients. The writer first tells us that Dr. Stewart's treatment was "founded upon every principle of common sense," that he "supported the constitution and enabled it to throw off the disease by its own rallying powers," and that as "the climate cannot

Through the kindness of Mr. Geo. W. Stewart, of Philadelphia, I was enabled to obtain the following concerning Dr. Way.

be brought to suit the constitution, therefore the constitution must be hardened to bear the climate." He favored rubbing the body with cold water and vinegar, believing that it hardened one, and allowed a liberal diet, though he did not favor the "cramming method." "It is Dr. Stewart's urgent wish," the letter continues, "that the patients should be for many hours daily in the open air—cautiously, however, avoiding fatigue—either on horseback, or on foot, or in an open carriage, which last he relies more upon as least likely to tire the patient." Can one conceive of more sound advice?

As might be predicted, such views aroused a storm of protest. He was "keenly opposed by the leading practitioners, both in Scotland and England." The following, abstracted from the minutes of the meeting of the Glasgow Medical and Chirurgical Society of February 17, 1825, shows how bitter was the feeling. A Mr. Campbell read a paper advocating the tonic treatment, but the majority present favored the antiphlogistic. "The society, in discussing this subject, naturally adverted to the chief promulgator of this practice—a medicoclerical gentleman of consumptive notoriety—who, by means of nourishing diet of the most substantial kind, with occasional use of wine and ardent spirits, aided by cold and tepid sponging, with as much exercise as the patient can bear, has effected so many wonderful cures and rendered his name famous over three kingdoms. If his practice has been so strikingly successful, he ought long ago to have sacrificed every feeling of personal aggrandizement to the public good, and, by publishing an account of his experiences, illuminated the darkened intellect of his medical brethren, removed those prejudices which many of the best informed entertain against it" (39).

When we consider that Dr. Stewart was serving in the dual capacity of physician and parson, we do not wonder that he did not find the time to "publish an account of his experiences."

Stewart died in 1838, and two years later George Bodington, a country practitioner of Sutton Coldfield, Warwickshire, England, read a paper before a medical society which was entitled "The cure of pulmonary consumption on principles natural, rational, and successful," in which he extolled the value of fresh air, restricted exercise, and an abundant diet. Although he made no reference to Stewart, it is more than probable that he had heard of him; for, as we have seen, his name was "famous over three kingdoms." Their views in the main were in accord, although Bodington allowed sedatives, which Stewart withheld, while the latter favored the employment of cold sponging and the use of vinegar, which the younger man did not refer to. Dr. Bodington established a sanatorium at Sutton, and for several years he treated consumptives with apparently considerable success. But the publication of this paper proved his downfall, for so bitter was the ridicule and so high did public opinion run that his patients left, and Bodington turned his institution—the first of its kind in the world—into an academy of the humane opera. It would be of more than passing interest to know how many of his medical brethren had subsequently had his patients.

Although Bodington was forced to close his sanatorium, his efforts can scarcely be said to have re-

sulted in a complete failure, for a young German, Herman Brehmer, was much impressed with the paper and he determined to found a sanatorium in Germany where the new treatment could be carried out. He encountered stubborn resistance, but he triumphed, and in 1854 established a magnificent sanatorium at Görbersdorf. And, as a result of Brehmer's success, we have sanatoria to-day all over the world.

In Ireland Graves enjoined his patients not only to walk and ride, but to sit out of doors quietly for several hours each day, thereby inaugurating the rest cure years before Dettweiler advocated it (41). The importance of rest is at the present time quite generally appreciated, and such exercises as mountain climbing and horseback riding are only recommended to those patients in whom all signs of activity have subsided. But the time was, a few years ago, when the most common advice given to the consumptive, irrespective of his condition, was "go west and ride horseback." Sydenham was one of the strongest advocates of horseback riding. "I sincerely assert," he says, "mercury in the French pox and Jesuit's bark in ague are not more effectual than the exercise above mentioned in curing consumption, if the sick be careful and the sheets be well aired, and that his journeys are long enough" (42). Stoll, on the other hand, about the middle of the eighteenth century, solemnly stated: "If a consumptive patient mount his horse he will ride to the bank of the Styx" (43).

The only son of Louis XV died of tuberculosis in 1765, and shortly after his death his wife developed the same disease. Throughout the greater part of her illness she was closely housed in the palace at Versailles and treated along antiphlogistic lines. When the malady had reached an advanced state Tronchin, a pupil of Boerhaave, was called in, and his substitution of a régime of fresh air and bountiful diet brought about a temporary improvement in her condition. But, the disease being far advanced, she soon succumbed to it. Tronchin had made many enemies by his radical change in the treatment, and when his royal patient died he was called "the worst of charlatans," and his treatment was designated as being "as fantastic as murderous" (44).

This backward glance into the treatment of tuberculosis would be incomplete were no reference made to the man who is the father of the sanatorium movement in this country—Dr. Edward L. Trudeau. Broken in health, he went into the Adirondacks in 1874, and while "taking the cure" through the long winter days he conceived the idea of a sanatorium where those of limited means might regain their health. The story of his struggles, his sore disappointments, his perseverance, and at last his success, is familiar to the profession. It is a tale of rare interest, and therein is depicted a lifelong devotion to a noble case that is rarely equaled.

After cleansing the parts, the urethra was flooded with normal salt solution, followed by an injection of four per cent. solution of cocaine. Finally an injection was given of olive oil. An attempt to dilate the urethra with sounds and to deliver the calculus by external expression failed; as did also attempts to withdraw or crush it by means of long armed nasal forceps introduced through the meatus.

The patient was given ether, and when fully anesthetized, a medium external urethrotomy was made directly over the foreign body. The stone was very irregular and jagged in shape, and was firmly imbedded in the urethral mucosa, forming a pouch from which it was extracted, piecemeal only, by much force and manipulation. Several smaller granules were found more deeply imbedded, and were also removed.

The wound was irrigated freely with boracic normal salt solution, and a metal catheter was then passed through the meatus into the bladder, which had in the meantime emptied itself through the wound. Using the catheter as a sound, it was impossible to detect other calculi in the bladder. The urethra was closed over the catheter by two fine silk sutures, prepared in the tincture of iodine. The outside wound, which passed partly through the raphe of the scrotum, was packed with gauze, soaked in alcohol, and a large gauze and cotton pad was applied.

Hexamethylenamine (urotropin), 65 centigrammes, was administered four times a day for a week. Magnesium sulphate was given several times to keep the bowels open. A light diet was maintained. The temperature was very irregular, being between normal and 101° F. for three days, when it finally became normal. The urine escaped in part through the wound until the eighth day. The presence of the catheter caused, at first, frequent emptying of the bladder. The fragments of the stone were very sharp, irregular, and were found to be phosphatic in character. Its full size, when impacted in the urethra, was about that of a very small hazel nut.

The patient made a steady and rapid recovery. The metal catheter was replaced by a soft rubber one, on November 10th, and the patient was discharged well on November 22d.

# EXTERNAL URETHROTOMY FOR ACUTE RETENTION OF URINE CAUSED BY IMPACTION OF A VESICAL CALCULUS IN THE PENILE PORTION OF THE URETHRA.

BY J. A. WOODBURY, M.D.

Assistant Surgeon, U.S. Army.

St. Louis, Mo., June 11, 1917.

A. M., a white, married, German, aged thirty-two years, was admitted to the St. Louis Marine Hospital, December 26, 1907, suffering with pain in the right side of chest. There had been no rise of temperature.

December 28. Pain in side improving. No fever. Patient well. He had been in Germany until 1905. Frequently ate fish from fresh water. He had been in the United States for three years. He had been in the United States for three years. He had been in the United States for three years.

At the time of admission, the patient was in good health. He had been in the United States for three years. He had been in the United States for three years. He had been in the United States for three years.

## A CASE OF MULTIPLE TAPEWORM INFESTATION.

BY R. E. WILSON, M.D.

New Orleans, La.

Received for publication, December 28, 1917.

Patient, male, age thirty-nine, was admitted to the United States Marine Hospital, New Orleans, La., December 26, 1907, suffering with pain in the right side of chest. There was no rise of temperature.

December 28. Pain in side improving. No fever. Patient well. He had been in Germany until 1905. Frequently ate fish from fresh water. He had been in the United States for three years. He had been in the United States for three years. He had been in the United States for three years.

At the time of admission, the patient was in good health. He had been in the United States for three years. He had been in the United States for three years. He had been in the United States for three years.

defecate into a vessel containing water at about body temperature. At 3 p. m. a large mass of worms passed.

December 31. Examination showed thirteen heads and 319 measured feet of worms. *Dibothriocephalus latus*. On account of the tangle in the worm mass and its having been immersed in water for several hours, no individual worm could be extricated complete. The longest unbroken length was seventeen feet.

January 2, 1908. Patient eating, sleeping, and feeling much better. Discharged, recovered.

The identification of the worms was based on the appearance of the heads, the size and shape of segments, the rosette uterus, and the appearance of the eggs. This finding has been corroborated by the pathological laboratory of the medical department, University of Texas, where specimens were deposited.

#### UNITED STATES MARINE HOSPITAL.

### Therapeutical Notes.

**Intramuscular Injections in Syphilis.**—After a trial of the soluble salts of mercury, J Ernest Lane (*The British Medical Journal*, March 21, 1908) has abandoned them for the insoluble preparations, using almost exclusively calomel. The dosage of the calomel is  $\frac{3}{8}$  grain of the sublimed powder suspended in 17 minims of sterilized olive oil, each injection being prepared separately and introduced into minute flasks hermetically sealed. The deposit of calomel seen in the small flasks at once disappears on heating them over a spirit lamp, when the powder assumes a milky appearance, and the powder is in a state of perfect suspension. He has also used gray oil, a term applied to a large number of preparations of different strengths and compositions, but consisting essentially of metallic mercury suspended in some fatty vehicle. He gives the following as the formula of a preparation which is employed by the army medical staff:

- R Mercury, ..... 3i;  
Wool fat, ..... 3iv;  
Liquid petrolatum (carbolized 2 per cent.), ..... ad 3x.

M.

One grain of metallic mercury is contained in 10 minims, and a suitable weekly dose for an adult is from 10 to 15 minims.

**The Purification of Drinking Water.**—Simple methods for the rapid purification of potable water continue to be published. French chemists have devoted much attention to the subject, and various means have been suggested of sterilizing the water of the Seine, which is greatly contaminated, being notable for the number of bacteria which it contains. Mention has been made in this column previously of a simple method, consisting of the addition to each quart of water of one grain of potassium permanganate, followed, after standing ten minutes, by the addition of two grains of manganous sulphate, which has the effect of precipitating all germs and impurities to the bottom of the vessel. Water treated in this way is freed from microbes and forms a limpid, colorless fluid of pleasant taste, which is richer in oxygen than ordinary water. A more efficient method of treating suspected water is described

by M. Célestin Hy in the *Union pharmaceutique*. The process is based upon the fact that potassium permanganate in an alkaline solution oxidizes organic matter and destroys microorganisms, just as in the preceding formula. The method is based on that originally devised by M. Girard and M. Bordas. The water to be purified is first treated with a powder consisting of one equivalent of potassium permanganate and sodium carbonate and slaked lime, of each seven equivalents. After an interval of five minutes eight equivalents of dried ferrous sulphate are added. Any calcium sulphate that may exist naturally in the water is precipitated by the sodium carbonate, while calcium bicarbonate is thrown down by the calcium hydroxide, the addition of ferrous sulphate removing any excess of permanganate in the form of a dense precipitate. Carefully decanted water treated in this way is said to be very pure and limpid and to contain a small amount only of the sulphates of potassium and sodium, the presence of which is not at all objectionable.

**Iodotannin Mixture for Tuberculosis.**—The following mixture is credited to Arthaud in *Journal de médecine de Paris* for February 22, 1908:

- R Tincture of iodine, ..... 3i;  
Tannic acid, ..... 3vi;  
Glycerin, ..... 3v;  
Alcohol, ..... 3x.

M. Sig.: One teaspoonful three times a day.

**Application for Neuralgic Headache and Inter-costal Neuralgia.**—An application used by Solis-Cohen, and which he has found of special value in neuralgic headache and intercostal neuralgia, is quoted by the *Journal of the American Medical Association* from *Merck's Archives*, as follows:

- R Oil of wintergreen, ..... aa 3i;  
Guaiaac, ..... aa 3v;  
Menthol, ..... gr. x;  
Hydrated wool fat, .....  
Cerate, ..... aa 3ii.

M. (Dispense in a tin tube.)

Sig.: A small quantity, about the size of a pea, to be well rubbed in over the seat of pain night and morning.

**Tonic Mixture for Phthisical Patients.**—To increase the appetite, control the fever, and overcome the cachexia, it is recommended in *Therapeutische Rundschau* for March 29, 1908, to administer the following mixture:

- R Quinine hydrochloride, ..... 3ss;  
Calcium hypophosphite, ..... 3i;  
Tincture of nux vomica, ..... 3iiss;  
Glycerin, ..... 3ii;  
Distilled water, ..... q. s. ad 3xvi.

M. Sig.: Two tablespoonfuls three times a day, half an hour before meals.

**The Administration of Calcium Lactate.**—According to *The Prescriber*, this salt should not be prescribed as powders or tablets, since, though soluble in water when freshly prepared, it rapidly becomes insoluble. The best method of administration is in solution as follows:

- R Precipitated calcium carbonate, ..... 3i;  
Lactic acid, ..... cxxx;  
Water, ..... enough to make 3vi

Solve. One tablespoonful contains fifteen grains of calcium lactate.

## A PROPOSED INCREASE IN THE RANK AND PAY OF OFFICERS OF THE ARMY MEDICAL DEPARTMENT.

We print in our Miscellany department the text of a measure providing for the reorganization of the Medical Department of the United States Army which has been approved by a conference committee of the two houses of Congress, and which it therefore seems reasonable to suppose will become a law. The measure has been before two sessions of Congress, and was passed by the Senate at a previous session. The main features of the bill are an increase in the number of medical officers and the provision for a medical reserve corps. The bill is eminently conservative, and was evidently drawn with a careful view to avoidance of arousing antagonism by the introduction of radical changes.

Another measure now before Congress which is of material concern to the medical officers of the Army and likewise of the National Guard is the Army pay bill, which provides for an increase in the rate of pay, both for enlisted men and for officers. This measure is also in the hands of a conference committee, and, as the principal difference between the bills passed by the Senate and by the House is in the form in which the increase of pay of the officers is stated, it seems reasonable to hope that the conference committee will come to an agreement, and that the bill as agreed on in conference will become a law. The Senate measure

provides that the present pay of officers of the Army shall be increased as follows: "Of brigadier generals, 15 per centum; of colonels, lieutenant colonels, and majors, 20 per centum; of captains, first lieutenants, and second lieutenants, 25 per centum." The measure passed in the House of Representatives, known as the Nelson Amendment, has the advantage that it disposes of the controversy over mounted and dismounted pay, giving in each case the actual amount of pay to be given to the officer in each particular grade, instead of stating this by means of a percentage increase. In most of the grades named the pay provided is the same in both bills, and where any difference exists the difference is small.

It is much to be hoped that both the pay bill and the reorganization bill will become laws, as it may then become possible to secure something like an adequate number of medical officers for the Army. Even had the reorganization bill passed, we doubt whether it would have been possible to secure as many medical officers as are provided for in that measure without some increase in the rate of pay, and this increase is provided in the Army pay bill, which thus becomes a very important factor in the contemplated reorganization of the Medical Department. The combination of an increase in the number of commissions in the higher grades in the department, which is provided for in the reorganization bill, and of an increase in the pay of officers of all ranks, provided for in the Army pay measure, may prove sufficiently attractive to induce the right kind of men to enter the service in sufficient numbers to meet the requirements of the Army.

## THE FRENCH SPEAKING PHYSICIANS OF NORTH AMERICA.

We long ago expressed our satisfaction at the establishment of the *Association des médecins de langue française de l'Amérique du Nord*. It is an organization that has a very legitimate place, and we are sure that it is doing good work. It is to be supposed that the French language is more extensively employed in the ordinary affairs of life in the Province of Quebec than elsewhere in North America, and in Quebec there are published several very creditable medical journals printed in French. The tercentennial of the founding of the city of Quebec is to be marked by a series of festivals beginning on the 20th of July. It is fitting, therefore, that the association is to hold its meeting at the same time in that old and picturesque city. The sessions will be held in the buildings of Laval University on the 20th, 21st, and 22d of the month mentioned.

There is a goodly number of French physicians in the United States—French by descent if not by birth—and they are among the most respected of our profession. Many of them will doubtless deem it almost a pious duty to betake themselves to Quebec on the occasion of the celebration, and not a few of our physicians who are not of the French race are sure to be attracted to the romantic city at the same time. Those of us who have ever visited Quebec preserve the memory of the geniality of our confrères resident in that region, and we always feel tempted to renew our acquaintance with them. It is not mere fondness for sight seeing that draws so many American visitors to Quebec; it is a genuine interest in the affairs of the people of the province and sympathy in their aspirations. All these things taken into consideration, we cannot doubt that the association's meeting this year will be a notable event.

#### NEW YORK'S TRIBUTE TO ROBERT KOCH.

It is granted, but seldom to a man to "read his history in a nation's eyes." Too often those who have given their lives in some work of humanity have known only a few friendly words among the jibes of many, and it has been reserved for another generation to honor their tombs. Again, those who have won the acclamation of the crowd, riding victorious from the fields of battle, have been followed by the lamentations of the conquered, the requiem of the slain. We can conceive of no honor greater or more soul satisfying than that which was brought to Dr. Robert Koch at this first public appearance in New York, though under the conventional tribute of a dinner given by the German Medical Society. From the head of the German nation and the leader of American industry, down to the humblest laborer who had suffered and been saved by some one of the 500 physicians present, there was a tribute of more than admiration, something very like worship, for the modest man of genius.

The abstract scientist, who follows the call of inquiry, is led into fascinating by paths, that may or may not lead to practical results. But Dr. Koch has had the genius of a philanthropist as well as a scientist. He has applied himself to the scourges of man and of animals that man depends upon. Humanity recognizes vaguely the value of thought, but thought that begets action, science that culminates in deeds—this they know to be the flower of civilization.

As Dr. Koch himself said, in answer to the words of praise and thanks that made the tribute

of our nation as represented by its physicians, he has never done anything more than all the doctors present were doing every day. He did his duty, they did theirs. That was all there was to it. And yet all the doctors present, cheering him, in their hearts knew the general who had led them, knew better far than the masses who have been brought back to health the infinite patience and courage necessary to surmount the difficulties that stand between a scientific discovery and its practical application. The appreciation of the scope of Dr. Koch's work, as shown in the speeches of such men as Dr. Welch, who studied under Cohnheim in the early days when Dr. Koch was working upon his germ theory, and of Dr. Jacobi, brought out the facts that Dr. Koch had shown the mind of a genius in his youth, and has unwaveringly devoted this genius to science on behalf of civilization. He has had a heaven born quality that is not always combined with genius, that of inspiring other men to work with him. Many of the most distinguished bacteriologists of our country have been students of Dr. Koch's in bacteriology, and there is not a laboratory the world over that does not owe some of its enthusiasm and power to men who have been guided by him.

From the days of miracles, how few the years, how great the progress! When plagues raged, a pilgrimage with a saint's relics at its head marched to a shrine, sowing disease through the country as it went. To-day, holy men—for the primitive form of the word holy meant bringing health, safety, happiness—men consecrated to a life of work, withdraw from the diversions and gratifications of life, and after years of labor, endeavoring to penetrate the mystery, their high priest steps forth, and reads a riddle of the ages, not in oracular words, but in the plain language of the people. In the emotional period of civilization's development, the masses would have rushed forth with huzzas, to greet the savior who healed them. None the less are they now saved, and none the less are they grateful, though to the high priest of science in this more moderate age no further demonstration is made than the hearty hand clasp and the word of thanks from the men who know

---

#### NEW ENGLAND AND THE SOUTH SHOULDER TO SHOULDER.

The president of the Society for the Protection of New Hampshire Forests, in a communication which he has had the courtesy to send us, asks us to help in securing national legislation for the preservation of some of our forests by calling at-

tention to the apparent unwillingness of Congress to act upon House bill No. 10457, entitled the White Mountain and Appalachian Forest Reserve Bill. He incloses a circular addressed to the members of Congress from the New England States, signed by the representatives of twelve great manufacturing concerns having their headquarters in or near Boston, in which we find this passage: "We beg to say that we believe the future welfare and prosperity of the eastern part of the United States, and especially of New England, to be dependent upon the adoption of the policy set forth in this bill, and that, if such policy is not adopted now, it will be necessary to adopt it at a future time and at vastly increased expense, and that in the mean time great injury will be done New England."

President Rollins reminds us that the bill has been endorsed by the entire country, and been urged for five years by lumbermen, paper makers, farmers, business men, and the press. He adds that at a recent hearing before the present Committee on Agriculture the governors of Georgia and New Hampshire, together with official delegates from the governors of twelve other States and a group of two hundred business men and citizens from all but four of the States that lie east of the Mississippi River, presented evidence that the timber supply was disappearing, that water powers were affected, that navigation was crippled, and that agriculture in the low lands, particularly in the South, was in many cases being ruined by floods. "When," says Mr. Rollins, "six New England States and eight Southern States unite in asking prompt action by Congress, do the men who guide that body propose to turn the matter calmly down? What do the representatives from the South and from New England intend to do about it?"

We believe that Mr. Rollins is quite warranted in using this strong language. We have always advocated legislative measures for the protection of our forests, and we now again adjure Congress not to disregard further the necessity of enacting House bill No. 10457. The sanitary advantages of the primeval forest are appreciated by the medical profession, and its necessity to great industrial enterprises is clearly understood. We cannot conceive of any good reason that can be entertained by Congress or its committees for standing in the way of such conservative and beneficent measures as this one for which the people of New England and the South are urgent. It is easy to destroy a forest, but it is a difficult and protracted task to restore one. Let not Congress delude itself with the notion that the advocates of the bill are actuated solely or even chiefly by æsthetic considerations, powerful as such considerations are and ought to

be. The reasons which impel them are practical and vital. Surely Congress should not adjourn without enacting the bill.

#### THE SIGNIFICANCE OF INTRACELLULAR TUBERCLE BACILLI IN THE SPUTUM.

Since the publication of Lowenstein's observations on the occurrence of tubercle bacilli in the pus cells of certain specimens of sputum (*Zeitschrift für Tuberkulose*, x, p. 47), this phenomenon has been generally regarded as a sign of favorable prognostic portent, as it was supposed to indicate phagocytic activity. A recent report by Pfeiffer and Adler (*Zeitschrift für Tuberkulose*, xii, p. 89), however, tends to discredit this supposition. In an examination of 844 specimens of sputum these authors found intracellular bacilli in forty-eight, from forty patients. The great majority of these patients were in an advanced stage of the disease, thirty-two presenting evidences of cavity formation, and in most of them the disease progressed rapidly to a fatal issue. All the sputa in which were found intracellular bacteria contained very numerous extracellular organisms, and Pfeiffer and Adler came to the conclusion that no more could be inferred from the presence of tubercle bacilli within the pus cells than from a great abundance of these organisms in the sputum.

#### THE OCULAR SYMPTOMS OF SCLERODERMIA.

Observations of abnormalities of the muscles of the eye associated with generalized scleroderma seem to have been recorded in but few instances, for M. Raymond and M. Guillaïn (*Bulletins et mémoires de la Société médicale des hôpitaux de Paris*, March 12th) declare that they have found parietic eye symptoms mentioned by Logetchnikov alone among recent dermatological writers. They themselves have observed two instances. They describe the paresis (sometimes amounting to absolute paralysis) as affecting the extrinsic muscles of the eye indiscriminately, but as being most decided in the external recti. Efforts to move the eyeballs are apt to be associated with oscillatory movements resembling those of nystagmus.

It is well known, the authors remark, that muscles are prone to become parietic as the result of scleroderma, and it is not those muscles alone that underlie the sclerotic skin, but others also that are situated at some distance. The trouble they think is in the muscles themselves rather than in the central nervous system. The paresis has been observed to disappear in cases of recovery from the scleroderma.

## A DINNER TO DR. ROBERT KOCH.

Robert Koch received a rousing welcome at a banquet arranged in his honor by the Deutsche medizinische Gesellschaft der Stadt New York at the Waldorf-Astoria on Saturday evening, April 11, 1908. Dr. Carl Beck, as president of the German Medical Society, presided at the dinner, in which about 450 admirers of the German savant took part. On the right of the guest of honor sat Mr. Andrew Carnegie.

Robert Koch's career is too well known to be mentioned in detail. Born at Clausthal on December 11, 1843, he received the usual medical education, and was county physician at Wollstein from 1872 to 1880. In his little town, removed from all the centres of medical science, he became interested in bacteriological studies, and discovered the anthrax bacillus in 1876. Thus, without a university career, he became soon a prominent figure in the medical profession. In 1880 he was called to Berlin as a member of the Imperial Department of Health. Two years later he published his discovery of the tubercle

bacillus, and in 1883 that of the comma bacillus, while he was chairman of the German Cholera Commission in Egypt. At the same time he found also the bacillus of Egyptian trachoma. In 1885 he was appointed professor and director of the Hygienic Institution at the University of Berlin, and in 1891 director of the Institution for Infectious Diseases. In the same year he published his first report on tuberculin. In 1896 the Cape Colony called him to southern Africa, where the rinderpest was threatening to destroy the cattle. He devised a virus suitable for protective inoculation. From there he went to Bombay to investigate the plague, and again to Africa, studying the cattle plague in German East Africa. He also began there his researches on malaria, which he continued in Italy, the Dutch East Indies, and New Guinea. Returning to Berlin, he took up the typhoid fever question, and was called back to Africa in 1903, and again in 1906, to study the sleeping sickness, which he definitely attributed to a trypanosoma. From that expedition he returned only a short time ago. He is now enjoying a long deserved rest, making a tour around the world. Such are the labors of Robert Koch! Modestly he said in his speech at the dinner:

Wenn ich Alles zusammenfasse, was zu meinem Lode heute gesagt worden ist, und die grosse Auszeich-

nung, die Sie mir zu Teil werden lassen, in Betracht ziehe, so entsteht in mir das Bedenken, ob ich auch wirklich berechtigt bin, mich so feiern zu lassen. Manches von dem, was mir Rühmliches nachgesagt wird, kann ich, wie ich glaube, mit gutem Gewissen acceptieren. Aber ich habe nichts Anderes gethan, als was Sie jeden Tag thun, nämlich ich habe gearbeitet was ich konnte, und meine Pflicht und Schuldigkeit gethan. Wenn etwas mehr dabei herausgekommen ist, so liegt das daran, dass ich auf meinen Wanderungen durch das medizinische Gebiet auf Strecken stiess, wo das Gold noch auf dem Wege liegt. Es gehört allerdings Glück dazu, das Gold von dem Unedlen scheiden zu können, das ist aber kein besonderer Verdienst.

But to come back to the banquet. Professor Beck, as president, speaking in German, introduced Professor Koch. Among other things he said: "What your achievements in science have been, men who are capable of judging will tell us tonight. It will not be an easy undertaking, for what you have accomplished will hardly find its equal in medical history. With admiration and deep wonder we ask ourselves: How could one human brain succeed in creating so much? We stand before a building firmly erected and resting upon a solid foundation, an immense monument in its simplicity and greatness, so similar to your own character. The tempest of time will sweep over it and may leave here and there superficial scars, but its foundation is unassailable, and will never be shaken." . . .

A "hoch" to Professor Koch concluded the chairman's address, and he then introduced Professor W. H. Welch, of Baltimore, who spoke of Koch as investigator and teacher. "His work," he said, "is a combination of discovery for science and comfort for mankind. While Dr. Koch has always shown the stamp of a scientist in his work, he has never allowed his view to wander from what would be most practical for the benefit of men. His work has been a triumph for the experimental method in science." . . .

Dr. Beck then read a letter of regret from Dr.

great distinction conferred by you upon me, I must necessarily ask myself, Am I really entitled to such homage? I believe that I can accept, indeed, with a clear conscience many of the laudatory things said about me. But I have done nothing else than what you are doing every day. I have worked as hard as I could and have fulfilled my duty and obligation. If the success really was greater than is usually the case, the reason for it is to be found in the circumstance that I came in my wanderings through the medical field upon regions where the gold was still lying by the wayside. For time is necessary to be able to distinguish gold from the base metals, but that is no great merit.

DR. ROBERT KOCH.

Trudeau, and upon motion of Dr. Koch, seconded by Mr. Carnegie, a telegram was sent to Dr. Trudeau.

Professor Abraham Jacobi was the next speaker. "The nineteenth century," he said, "gave to medicine four epoch making men—Bichat, Virchow, Pasteur, and Koch; three for its clinical department: Virchow, Pasteur, and Koch; two for the modern knowledge of serum theory and prophylaxis: Pasteur and Koch. . . . We have the honor of having with us the only survivor of these four great men. . . ."

Professor Beck then read a letter from the German Ambassador in Washington to Andrew Carnegie, who was the next speaker. Mr. Carnegie said: "In viewing the progress of the world in its various phases, no profession has made and is making greater progress to-day than the art of healing. . . . In the list of the heroes of civilization our honored guest occupies a high position. The world has always been devoted to hero worship, ever prone to worship physical force as displayed in its heroes. These heroes, from the days of Homer, have been men who had become celebrated for the number of their fellow men they had butchered. . . . Our true hero of to-day is he who can count the number of men, women, and children he has saved. Jenner, Lister, Pasteur, Reid, Carroll, Lazear, Agramonte, and Koch are such heroes. . . ."

The last speaker of the evening was the guest of honor. His speech culminated in the following very interesting remark: "We have achieved all we could in our fight against tuberculosis. We have come to a point where we can hardly hope for more success. The idea of building sanatoria will not accomplish much; such sanatoria will only benefit certain localities. We must make new researches. Such researches will become possible in the Robert Koch Institute for Tuberculosis in Berlin, a foundation which Andrew Carnegie has so munificently endowed. In this institution investigations will be made which will open new fields, new theories, new modes and possibilities of fighting the old enemy, tuberculosis. It will be an international affair, benefiting all mankind. And we have to thank Mr. Carnegie for placing this institution upon a sound financial basis. *Herr Carnegie lebe hoch!*"

Professor Beck then closed the proceedings by proposing the health of Mrs. Koch, who had accompanied her illustrious husband to Africa, and is now with him on his trip around the world.

The company included between four and five hundred persons, of whom the following had been assigned to seats at the main table:

Professor Dr. Robert Koch, Exchelon, Berlin, guest of honor.

The President, Dr. Carl Beck.

Dr. I. George Adams, Montreal; Dr. Isaac Adler; Dr. Hermann M. Biggs; Mr. George Blumenthal; Dr. Vincent Y. Bowditch, of Boston; Consul General Bünz; Professor J. W. Burgess; Mr. Andrew Carnegie; Dr. Thomas Darlington; Dr. Francis Delafield; Dr. Simon Flexner; Dr. Lawrence F. Flick, Philadelphia; Dr. Frank P. Foster; Dr. William S. Halsted, Baltimore; Mr. R. W. Hoar; Dr. Abraham Jacobi; Dr. Edward G. Janeway; Dr. Howard A. Kelly, Baltimore; Dr. S. Adolphus Knopf; Geheimrat A. Martin, Berlin; Dr. Alfred Meyer; Mr. Henry Phipps, Philadelphia; Dr. William M. Polk; Dr. Eugene H. Porter, Albany; Dr. Theobald Smith, Boston; General George M. Sternberg, of the Army; Dr. Victor C. Vaughan, Ann Ar-

bor, Mich.; Dr. Leonard Weber; Dr. William H. Welch, Baltimore; Dr. John A. Wyeth; General Walter Wyman, of the Public Health and Marine Hospital Service.

## News Items.

**Changes of Address.**—Dr. S. A. Bienenstock, to 1542 Madison avenue, New York; Dr. J. E. Cannaday, from Wheeling, W. Va., to 1012 Virginia street, Charleston, W. Va.

**Medical Society of New Jersey.**—The annual meeting of this society will be held in Cape May on June 18th, 19th, and 20th, instead of June 23d, 24th, and 25th, as originally announced.

**Society of Physicians of the Village of Canandaigua, N. Y.**—At a meeting of this society which was held on Thursday evening, April 9th, Dr. H. I. Davenport read a paper entitled Pathological Physiology.

**Richmond, Va., Academy of Medicine and Surgery.**—At a regular meeting, held on Tuesday evening, April 14th, Dr. Karl von Ruck, of Asheville, N. C., read a paper entitled General and Specific Resistance to Tuberculous Infection.

**The Middlesex County, Conn., Medical Association** held its annual meeting on Thursday, April 9th, and elected the following officers for the ensuing year: President, Dr. James Murphy; vice president, Dr. M. D. Murphy; clerk, Dr. Arthur B. Coleburn.

**Hudson County, N. J., Medical Society.**—At the annual meeting of the society, which was held recently, the following officers were elected for the ensuing year: President, Dr. John J. Mooney; vice president, Dr. Arthur Haskins; treasurer, Dr. H. Brinkerhoff.

**Emanuel County, Ga., Medical Association.**—At the annual meeting of this association, which was held in Swainsboro on April 8th, the following officers were elected: President, Dr. J. W. Bowie, of Summit; secretary and treasurer, Dr. J. H. Chandler, of Swainsboro.

**The Society of Medical Jurisprudence, New York.**—At a meeting of this society, held on Monday evening, April 13th, Dr. Daniel Lewis, former Commissioner of Health of the State of New York, delivered an address on The Sanitary Protection of New York Bay.

**Buffalo, N. Y., Academy of Medicine.**—A meeting of the Section in Medicine was held on Tuesday evening, April 14th. Dr. John D. Bonnar read a paper on Apoplexy, and Dr. Julius Ullman read a paper on Psychotherapy. Dr. James W. Putnam, of Boston, opened the discussion.

**The Philadelphia Medical Club** held its regular quarterly reception on the evening of April 10th. Dr. Samuel G. Dixon, Commissioner of Health for the State of Pennsylvania, and Dr. Louis G. Filcher, of New York, were the guests of honor. About three hundred members were in attendance.

**The Pennsylvania Society for the Prevention of Tuberculosis** held its annual meeting on Wednesday, April 8th. Dr. Charles J. Hatfield was elected president of the society, Dr. James M. Anders, first vice president, and Dr. Ward Brinton, secretary. During the year contributions amounting to \$4,505.86 were received.

**The Harvey Society Lectures.**—The ninth lecture in the Harvey Society course will be given at the New York Academy of Medicine on Saturday evening, April 18th, at 8:30 o'clock, by Professor Alonzo E. Taylor, of the University of California. The subject will be The Role of Reversed Ferment Reactions in Metabolism.

**Windham County, Conn., Medical Association.**—The one hundred and thirty-third annual meeting of this society will be held in Putnam, Conn., on Thursday, April 23d, at 10 o'clock. The program includes the following papers: Diagnosis of Impetigo Contagiosa, by Dr. J. L. Gardner, of Central Village; an address on Bacteriology, by Professor H. W. Conn, of Middletown University; The Present Status of Serum Therapy, with Special Reference to Typhoid and Diphtheria, by Dr. John B. E. Smith, of Hartford. The officers of the society are: President, Dr. C. J. Le Claire, of Danielson; vice president, Dr. Robert C. Paine, of Thompson; secretary, Dr. James L. Gardner, of Central Village.

**Rochester, N. Y., Academy of Medicine.**—The regular monthly meeting of Section III, which embraces obstetrics, gynecology, and pediatrics, was held on Wednesday evening, April 15th. The principal paper on the programme was read by Dr. William M. Brown on Obstetrical Hemorrhages; Causative Factors and Methods of Control.

**Philadelphia Pædiatric Society.**—At a meeting of this society, which was held on Tuesday, April 14th, Dr. A. Parker Hitchens read, by invitation, a paper on Anaphylaxis; Dr. B. F. Boyer read a paper on Hypersusceptibility to Horse Serum in Man; and Dr. F. C. Knowles read a paper entitled Syphilis Extragenitally Acquired in Childhood.

**Hornell, N. Y., Medical and Surgical Association.**—At the nineteenth annual meeting of this Association, which was held on the evening of April 6th, the following officers were elected: President, Dr. Leon M. Kysor; vice president, Dr. J. G. Kelly; secretary, Dr. B. R. Wakeman. At the close of the meeting the members adjourned to the Hotel Sherwood, where the annual banquet was served.

**Physicians Wanted for State Hospitals and Institutions.**—The New York State Civil Service Commission will hold an examination on May 9th for the position of physician to State hospitals and institutions, with a salary of \$900 and maintenance. Applications must be filed on or before May 2d. Full information and application forms may be obtained by addressing Mr. Charles S. Fowler, chief examiner of the commission, Albany, N. Y.

**A New Laboratory for Clinical Pathology.**—The Saxe Laboratory was opened recently at 72 West Forty-fifth street, New York, under a charter granted by the State of New York. The object of this laboratory is to aid physicians in the diagnosis of disease. A course in clinical microscopy will be given to practitioners, and special research work in clinical pathology will be carried on under the supervision of the director, Dr. De Santos Saxe.

**Contagious Diseases in Chicago.**—During the week ending April 4, 1908, there were 57 cases of diphtheria reported to the Department of Health, a decrease of 48 cases from the preceding week. Scarlet fever cases showed a slight increase, 98 cases having been reported, as compared with 84 for the preceding week. There were 309 cases of measles reported during the week, and 80 cases of tuberculosis. Only one case of smallpox was reported.

**The Medicolegal Society of New York** will meet in joint session with the Psychological Section of the society at the Waldorf Astoria on Wednesday, April 22d, at 8:30 p. m. Mr. Andrew McConnell will read a paper on The Electrical Action of the Organs of the Human Body. Margaret Higgins, of New York, will read a paper on Psychotherapeutics in European Capitals. There will be a general discussion on Alcohol as a Diet or a Medicine, and Medical Expert Testimony.

**Medical Society of the County of Kings.**—A meeting of the Section in Pediatrics was held on Friday evening, April 17th. The programme included the following: Report of a case of hereditary syphilis treated with intramuscular injections of mercury, by Dr. F. B. Van Wart; a paper entitled Results of the Use of Antistreptococcus Serum in Scarlatina, by Dr. Henry T. Robinson, of Manhattan; A review of German pediatric literature for the year 1908, by Dr. Alexander Spingarn.

**Prize for Essay on Occupational Diseases.**—Dr. Lewis Livingston Seaman has offered a prize of \$100 for the best essay on The Economic Waste Due to Occupational Diseases. In the original announcement the time limit was specified as April 1st, but we are informed that the time has been extended to June 15th. Each essay should be submitted on one side of the paper, and should be enclosed in a sealed envelope to the Director of the American Medical Association, 535 North Dearborn Street, Chicago, Ill., and addressed to the West Thirty-ninth street, New York.

**Philadelphia County Medical Society.** The Central Branch of this society held a meeting on Wednesday evening, April 8th. The general subject for consideration was life insurance and medical practitioners, and papers were read as follows: The Various Forms of Life Insurance and Their Relation to the Medical Profession, by Dr. Charles M. ... The ... in the ... of New York ... the Medical ... of Man

ance Applicants, by Mr. J. Burnett Gibb, of the American Society of Actuaries; The Five Dollar Minimum Fee for the Medical Examination of a Life Insurance Applicant, by Dr. J. Norman Henry; Honor Roll of Life Insurance Companies Paying the Five Dollar Minimum Fee for Medical Examinations, by Dr. Ernest W. Kelsey. Among those who took part in the discussion were Dr. William Howard King and Dr. J. Allison Scott.

**Medical Society of the County of St. Lawrence, N. Y.**—The semiannual meeting of this society was held in Gouverneur, N. Y., on the evening of April 7th. At the close of the meeting a banquet was given by the members. Dr. Grant C. Madill, of Ogdensburg, presided as toastmaster, and among those who responded to toasts were Dr. E. A. Nevin, Dr. H. J. Morgan, and Dr. S. W. Close. The officers of the society are: President, Dr. James Wiltse, of Benson Mines; vice president, Dr. E. A. Nevin, of Ogdensburg; secretary, Dr. S. W. Close, of Gouverneur; treasurer, Dr. A. H. Allen, of Gouverneur.

**Charitable Bequests.**—By the will of Benjamin Whitman, of Erie, Pa., who died in Mexico City, recently, the Home for the Friendless and St. Joseph's Orphan Asylum, Philadelphia, receive \$1,000 each.

By the will of Miss Laura P. Willard, who died recently in Prescott, Canada, the Brockville General Hospital and the Toronto Hospital for Sick Children will each receive \$1,000.

By the will of Mr. William Wheeler Smith, who died recently in New York, St. Luke's Hospital receives the income from nearly \$3,000,000 worth of property in New York. On the death of Mrs. Smith the entire property reverts to the hospital.

**The Mortality of Chicago.**—According to the report of the Department of Health for the week ending April 4, 1908, there were during the week 637 deaths from all causes, as compared with 686 during the corresponding week in 1907. The annual death rate in 1,000 of population was 15.33. Of the total number of deaths 364 were of males and 273 of females. The principal causes of death were: Apoplexy, 19; Bright's disease, 51; bronchitis, 29; consumption, 59; cancer, 30; convulsions, 7; diphtheria, 7; heart diseases, 43; influenza, 8; intestinal diseases, acute, 32; measles, 3; nervous diseases, 24; pneumonia, 99; scarlet fever, 8; suicide, 13; typhoid fever, 7; violence (other than suicide), 31; whooping cough, 4; all other causes, 163.

#### Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Department of Health for the following statement of new cases and deaths reported for the two weeks ending April 11, 1908:

	April 4-11		April 11-18	
	Cases.	Deaths.	Cases.	Deaths.
Tuberculosis, pulmonary	531	17	57	11
Epidemic	360	14	368	65
Measles	1,728	37	1,877	48
Scarlet fever	997	27	984	24
Smallpox	106	8	166	1
Varicella	28	8	23	4
Typhoid fever	28	8	23	4
Whooping cough	9	1	1	1
Cerebrospinal meningitis	9	12	14	1
Totals	3,728	129	4,005	109

**The Health of the Canal Zone.**—The report of the Department of Sanitation of the Isthmian Canal Commission for the month of February, 1908, is at hand. During the month the population of the Canal Zone, including the cities of Colon and Panama, was 113,260, among whom there were 202 deaths, corresponding to an annual death rate of 21.40 in 1,000 of population. There were 2 deaths from typhoid fever, 10 from restivoautumnal malaria, 20 from clinical malaria, 1 from hemoglobinuric fever, 6 from clinical dysentery, 4 from beriberi, 2 from septicemia, 18 from pulmonary tuberculosis, 2 from other forms of tuberculosis, 1 from syphilis, 3 from cancer, 5 from tetanus, 4 from bronchopneumonia, 18 from pneumonia, 1 from other forms of pneumococcus infection, and 14 from diarrhea and enteritis, under two years of age. The death rate among the white employees was 7.12 in 1,000, and among the negroes it was 14.88 in 1,000. The morbidity rate among the employees was 17.86 in 1,000; in February, 1907, it was 24.73 in 1,000. Dr. Gorgas says at the end of his letter of transmittal: "Taken as a whole, this is the most favorable health report that the Sanitary Department has heretofore been able to give, and it has been on the Isthmus."

**Personal.** Dr. Stephen J. Maher has been appointed president of the board of health of New Haven, Conn.

Dr. Richard Mills Pearce, Jr., of Albany, N. Y., has been appointed professor of pathology and director of the laboratory of pathology at the University and Bellevue Hospital Medical College, New York.

Dr. William H. Davis has been appointed a general medical inspector of the board of health of Boston. He will devote most of his time to infectious diseases.

**Vital Statistics of New York.**—During the week ending April 4, 1908, there were reported to the Department of Health of the City of New York 1,497 deaths from all causes, corresponding to an annual death rate of 17.66 in 1,000 of population. Of the total number of deaths 830 were in the borough of Manhattan, 132 in the Bronx, 448 in Brooklyn, 69 in Queens, and 18 in Richmond. The principal causes of death were: Contagious diseases, 142; pulmonary tuberculosis, 171; pneumonia, 117; bronchopneumonia, 109; diarrheal diseases, 94; Bright's disease and nephritis, 115; organic heart diseases, 151; cancer, 63; apoplexy. There were 76 deaths from accidents, 4 from homicide, and 18 from suicide. There were 743 marriages recorded during the month, 2,724 births, and 143 stillbirths.

**Medical Society of the County of Suffolk, N. Y.**  
The semiannual meeting of this society will be held in Brentwood, N. Y., on Thursday, April 30th, at 11 o'clock. The programme includes the following papers: Conduction Aphasia, with the exhibition of the patient, by Dr. M. B. Heyman, of Central Islip State Hospital; Measurement of Blood Pressure, with demonstration of the apparatus, by Dr. Roland Hazen, of Brentwood; Methods of Gastric Diagnosis, with demonstrations of physical diagnosis and laboratory examinations, by Dr. Dudley D. Roberts, of Brooklyn. The officers of the society are: President, Dr. Arthur H. Terry, of Patchogue; vice president, Dr. Marcus B. Heyman, of Central Islip; secretary, Dr. Frank Overton, of Patchogue; and treasurer, Dr. Barton D. Skinner, of Greenpoint.

**New York Pathological Society.**—A regular meeting of this society was held at the New York Academy of Medicine on Wednesday evening, April 8th. Dr. G. B. Satterlee and Dr. S. O. Sabel reported a case of pernicious anemia with "hour glass" stomach treated by colon irrigation. Dr. O. H. Schultze reported cases of septic thrombophlebitis of the longitudinal sinus and impetigo contagiosa with septicæmia. Dr. H. Zinsser reported the following cases: Arteriosclerosis of the pulmonary arteries; metastatic sarcoma of the lungs with bone formation, and typhoid infection of the gallbladder. Miss A. Oppenheimer read a paper on Radial Fibres in Blood Vessels. Dr. James Ewing read a paper on Myxoma of the Full Term Placenta. Dr. E. Moschocowitz read a paper on Typhoid Fever with Mixed Infection: Unusual Intestinal Lesions. Dr. H. L. Celler read a paper on Lesions in a Case of Myxæmia Gravis.

**A Dinner to Dr. Wiley.**—The twenty-fifth anniversary of the service of Dr. Harvey W. Wiley as chief chemist of the United States Department of Agriculture was celebrated by a dinner given in his honor at the Hotel Astor on Thursday evening, April 9th, by some two hundred chemists of New York and vicinity. Dr. William Jay Scheffelin presided at the dinner. Congratulatory addresses were made by Professor W. D. Bancroft, of Cornell University; Professor Joseph P. Remington, of Philadelphia, chairman of the Committee of Revision of the United States Pharmacopœia; Professor M. T. Bogert, of Columbia University; Mr. C. F. Cox, president of the New York Academy of Sciences; Mr. Herman A. Mott, comptroller of the city of New York; Mr. Walter H. Page, editor of the *World's Work*; and others. The speakers lauded Dr. Wiley for his work in the national administration of the national food and drugs act. He was referred to as standing for the ideal of pure, unadulterated truth, and as being therefore naturally a student of science, mainly from the following evening, April 10th, the chemists of the city of Washington also honored Dr. Wiley, a banquet in their city in commemoration of his services to chemistry during the period of his study and practice.

**American Paediatric Society.** The twentieth annual meeting of the society will be held at the Waterbury Hotel, Delaware Water Gap, Pa., on May 14th, 15th, 16th, and 17th. The committee arranging to make this meeting one of unusual interest. On occasion will be depicted as follows:

ussion of the serum treatment of epidemic cerebrospinal meningitis. Dr. Simon Flexner will open the discussion, and Dr. Dunn will give a résumé of the results of this treatment as observed in the Children's Hospital in Boston. Another session will be devoted to the subject of the influence of cold air in the treatment of disease, the disease to which it is applicable, and the degrees of temperature which should be used in the different types of disease. Dr. Northrup and Dr. Graham will take part in the discussion. Sufficient time will be devoted to poliomyelitis anterior, especially as an epidemic, and Dr. Koplik and Dr. Le Fetra have consented to discuss the subject. Dr. Holt has promised a paper on Recent Diagnostic Methods in Tuberculosis in Children. With four such interesting subjects for discussion, the committee feels warranted in asking the members to attend papers on the different phases of the question. The committee is desirous of issuing the preliminary programme as soon as possible, and members are therefore requested to send the titles of their papers, at their earliest convenience, to Dr. Samuel S. Adams, 1 Dupont Circle, Washington, D. C.

### Society Meetings for the Coming Week:

MONDAY, April 10th. -New York Academy of Medicine (Section in Ophthalmology); Medical Association of the Greater City of New York; Hartford, Conn., Medical Society.

1953-54, April 1955: New York Academy of Medicine (Section in Medicine); Buffalo Academy of Medicine (Section in Pathology); Tri-Professional Medical Society of New York; Medical Society of the County of Kings, N. Y.; Binghamton, N. Y., Academy of Medicine; Clinical Society of the Elizabeth, N. J., General Hospital; Syracuse, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association.

WEDNESDAY, April 2d—New York Academy of Medicine  
(Section in Laryngology and Rhinology); New York  
Surgical Society.

THURSDAY, April 23d.—New York Academy of Medicine (Section in Obstetrics and Gynaecology); Brooklyn Pathological Society; Hospital Graduates' Club, New York; New York Celtic Medical Society.

Friday, April 5th. New York Clinical Society, New York Society of German Physicians; Academy of Pathological Sciences, New York.

SATURDAY, April 25th.—West End Medical Society; New York Medical and Surgical Society; Harvard Medical Society, New York; Lenox Medical and Surgical Society, New York.

**Meetings of Sections of the New York Academy of Medicine.**—The Section in Ophthalmology will meet on Monday evening, April 24th, at 8 15 o'clock, in the Academy. Knapp will present a specimen of melanosarcoma of the conjunctiva. Dr. E. B. Cohn will exhibit an apparatus to measure ocular tension, and Dr. Arnold Knapp will exhibit an apparatus to determine the color of the fundus of the eye. Dr. J. E. Weeks will demonstrate the method of testing the field of vision. The paper of the evening will be read by Dr. John E. Weeks on Plastic Operations on the Lids by Means of Flaps without Pedicle.

The following program has been arranged for the meeting of the Section on Medicine, to be held at the Hotel Marlborough, April 1st-3rd, 1907. The Association will meet at 10:30 a. m. on April 1st, at 10:00 a. m. on April 2nd, and at 9:30 a. m. on April 3rd. The following papers will be read:

**10:30 a. m., April 1st.**—**Diabetes Mellitus.** Dr. Henry L. Shively; **Neuralgia: Its Specific Treatment with Chloroform Subcutaneously.** Dr. S. O. Goldan. **Reports of Cases.** Pulmonary Artery Lesions with Hemoptysis. Dr. Haelew Brooks; **Pulmonary Emphysema, operative treatment.** Dr. Charles Goodhue.

**10:00 a. m., April 2nd.**—**Diabetes Mellitus.** Dr. F. R. McCreery.

[illegible]

## Pith of Current Literature.

### THE BOSTON MEDICAL AND SURGICAL JOURNAL.

April 9, 1908.

1. On the Significance of Clinical Histories Before and After Operative Demonstration of the Real Lesion,  
By MAURICE H. RICHARDSON.
2. Observation Hospital or Wards for Early Cases of Mental Disturbance,  
By L. VERNON BRIGGS.
3. A Case of Infantile Pyloric Stenosis with Autopsy Six and One Half Months After Successful Gastroenterostomy,  
By JOHN LOVETT MORSE, FRED T. MURPHY, and S. B. WOLBACH.
4. A Case of Congenital Stenosis of the Pylorus,  
By CHARLES W. TOWNSEND.
5. The Scope of Therapeutic Inoculation,  
By G. P. SANBORN.

3. **A Case of Infantile Pyloric Stenosis.**—Morse, Murphy, and Wolbach describe such a case. The cause of death was a general peritonitis without demonstrable anatomical cause. Special attention was given to the tissues about the gastroenterostomy, both at the autopsy and afterward in going over the hardened specimen. The condition of the gallbladder, appendix, and gastrointestinal tract ruled out infection from these sources. The negative findings in the dissection of the spermatic cords and seminal vesicles made an infection from the penis very improbable. Normal pleural and pericardial cavities excluded these as sources of infection. Finally, the absence of any older localized process, and the diffuse, even distribution of the exudate forced the authors to the conclusion that the infection took place through a vascular route. The infecting organism, judging from the morphology in sections, could be either the pneumococcus or the streptococcus, probably the former. The microscopical findings in the pylorus were surprising, because of absence of degenerative changes in the smooth muscle, either in the form of atrophy or in connective tissue overgrowth. The closed state of the pylorus was proved by the mechanical tests applied and by the rigidity and thickness of the walls, which were in striking contrast to the usual post mortem condition of the pylorus in infants. The flattening of the mucosa could hardly be considered as an evidence of permanent closure. The cystic dilations of the glands were probably mechanical in origin, though a few similar cysts have been seen in the mucosa of the normal pylorus of infants. In the case of an infant a few weeks old, operated upon for pyloric stenosis and which died a few days later, only slightly dilated pyloric glands were found. This fact supports the belief that in the case our authors reported the long continued closure of the pylorus was the cause of the glandular dilatation. The case is in so far interesting as it is the first one reported where any one had had the opportunity of studying the anatomical conditions in a case of infantile pyloric stenosis at so long a time as six and one half months after a successful gastroenterostomy. This case, the authors conclude, proves that, in some instances, at least, the stenosis is not due to spasm, that medical treatment cannot be of any avail, and that the only hope for relief and life lies in surgical intervention. It also proves that an infant can live and thrive for many months, although all the food passes through the gastroenterostomy opening and none through the pylorus. It suggests

that the condition of organic infantile pyloric stenosis is a permanent one, that there is no tendency toward a restoration of normal conditions, and that there is little hope of the pylorus ever resuming its functions. It is not safe to draw conclusions from these suggestions, remark the authors, as it is possible that, with the lapse of time and the growth of the parts, changes may occur which will result in the restoration of normal conditions and function. These points can only be decided by the actual observation of the anatomical conditions in cases dead at longer intervals after successful operations.

### THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

April 11, 1908.

1. Pancreatitis Resulting from Gallstone Disease,  
By WILLIAM J. MAYO.
2. Detection of the Emotions by the Galvanometer,  
By E. W. SCRIPTURE.
3. Plague Among Rats in San Francisco,  
By WILLIAM B. WHERRY, AGNES WALKER, and EDGAR H. HOWELL.
4. Ocular Rotations in Paresis,  
By FRANCIS VALK.
5. The Treatment of Interstitial Keratitis,  
By H. H. MARTIN.
6. Disturbance of Nitrogenous Metabolism in Epilepsy,  
By A. J. ROSANOFF.
7. Intussusception and Its Cause,  
By W. L. WALLACE.
8. Passive Hyperemia of the Lungs and Tuberculosis,  
By WILDER TILESTON.

3. **Plague Among Rats in San Francisco.**—Wherry, Walker, and Howell agree with the last Indian Commission that, with experience, the chances of missing a plague infected rat by the naked eye method of examination alone are extremely small. Recently the authors have abandoned the wholesale preliminary microscopical examinations and substituted the anatomical dissections, followed by the bacteriological and animal tests of anatomically suspicious rats. Of 14,184 rodents examined, 98.97 per cent. were *M. decumanus*; 0.73 per cent. *M. rattus*; 0.35 per cent. *M. rattus alexandrinus*, and 0.11 per cent. *M. musculus*. By far the greater number found infected were *M. decumanus*. The results of animal inoculation experiments show that the bacillus of natural rat plague in San Francisco is quite as virulent as the strains tested in Bombay by the last Indian Commission. Complete post mortem notes on eighty-eight "positive" rats showed that seventy-four of these had enlarged and congested glands; thirteen of the seventy-four showed a typical primary bubo (six inguinal, one submaxillary, one axillary). Only twenty-eight presented the characteristic anatomical picture of general subcutaneous congestion, enlarged and congested glands, splenic tumor, and hydrothorax or hemothorax. The inguinal glands, either alone or along with other glands, were enlarged and congested in forty-seven, the axillary glands in thirty, and the submaxillary glands in thirty-three instances. No single characteristic abnormality invariably occurred in the rats of this series. Most of the eighty-eight rats were fresh; only seven showed much post mortem decomposition, and in these typical bacilli were fairly numerous, either in the spleen or in a gland.

4. **Ocular Rotations in Paresis.**—Valk concludes that all tests for paresis must be made with the look in complete infinity and with full acuity of vision. We must have a standard of the field of vision for comparison of any deficiency of rotation.

The straight muscles are capable of moving the eyes in any part of the field of vision and from one part of the field to another; in other words, in no part of the field will the straight muscles fail to act according to their usual function. The obliques take no part or action in the rotation of the eyes in the field of version; in other words, the oblique muscles do not elevate or depress the visual line. A distinct line must be drawn between paresis and heterophoria as shown by the diplopia; in the first by diplopia in infinity and in the second by the possible diplopia with reduced vision. In the consideration and diagnosis of paresis we may exclude the condition of crossed or homonymous images and also the tipping, except in a pathological condition of the obliques. The individual muscles of the eyes are not endowed with two distinct functions, as they have but one nerve supply, except possibly in the action of convergence and inward rotation due to two distinct nerve centres. The points of action of the straight muscles of the eyes are the insertions and the sheaths of the tendons as they are situated in the orbit just behind the globe.

**7. Intussusception and Its Cause.**—Wallace states that the typical symptoms of intussusception are pain, shock, small, bloody mucous stools, with tenesmus and characteristic tumor. In his case pain was not a prominent symptom, and there was no discharge from the bowels, no inclination to move the bowels, and no tumor could be felt, even under an anæsthetic. A child may have bloody mucous stools without intussusception, and, on the other hand, an intussusception may slough away without the appearance of bloody stools. The usual ileocecal intussusception forms a palpable tumor, but an enteric intussusception may be so small or high that a tumor cannot be appreciated. In his case an unusual symptom was present—frequent bloody vomiting. In regard to the cause of intussusception, observation and experiment show that invagination is of frequent occurrence and is easily produced by slight irritation of the normal intestine, the bowel above rolling into the segment below and emptying itself as in a movement of the bowels. Treves goes so far as to hold that many attacks of indigestion may be due to a temporary invagination of the bowel, in which case the circular fibres below rapidly contract and reduce the intussusception before adhesions form between the layers. Whatever would prevent the reduction of this physiological invagination would produce a true pathological intussusception. There are two theories of the cause of intussusception: spasm and paralysis. The first theory holds that, for some reason, a local spasm is set up in the bowel and a violent contraction takes place, and this point is made the apex of an intussusception by passing into the intestine below or having the bowel below drawn up outside. The other theory is that of paralysis. A certain section of bowel is paralyzed by interference with its nerve or blood supply. It, therefore, becomes distended and the bowel above is pushed into it.

**8. Passive Hyperæmia of the Lungs and Tuberculosis.**—Lileston states that one hundred and twenty eight cases of mitral stenosis at autopsy showed a much lower percentage of pulmonary tuberculosis than the material from which they were

drawn. Those cases with a high degree of stenosis were more free from tuberculosis than those with a moderate stenosis, and were entirely exempt from active tuberculosis. A person with mitral disease is less liable than others to acquire tuberculosis of the lungs, and if he does, the pulmonary disease usually runs a mild course, with a strong tendency toward cure. This relative immunity is to be ascribed to passive hyperæmia of the lungs consequent on the mitral lesion. There is a possibility that artificially induced hyperæmia of the lungs may be a valuable adjunct in the treatment of pulmonary tuberculosis.

#### MEDICAL RECORD.

April 11, 1908.

1. Diabetes and the Food Factor, By HENRY S. STARK.
2. Spontaneous Gangrene of the Foot Due to Enderteritis Obliterans, By ISAAC LEVIN.
3. The Relation of Appendicitis to Gynecological Pelvic Diseases, By SAMUEL WYLLIS BANDLER.
4. Blood Pressure in the Practice of Medicine, By W. FOREST DUTTON.
5. Health of Our High School Children, By ELIZABETH JARRETT.
6. The Solution of the Lodge and Society Problem of the East Side, By JULIUS WEISS.
7. A Case of Cut Throat, By CHARLES I. PAGE.

**1. Diabetes and the Food Factor.**—Stark states that as far as the dietetic treatment of diabetes is concerned, we should not lose sight of the one cardinal fact, that total or partial failure to assimilate carbohydrates is the salient phenomenon of the disease. The principle involved in the treatment, then, must be to lessen the carbohydrates in the food, until the sugar disappears, if that is possible, and afterwards tentatively to replace them, noting the effects of each addition on the urine, as a guide to future dietary measures. In order to carry this principle into effect it is necessary to ascertain experimentally the patient's ability to assimilate carbohydrates. For purposes of estimating, approximately, of course, this tolerance, several methods are employed, the most familiar of which is that known as von Noorden's standard test diet. This diet consists of three meals, carried out for one or two days, of articles free from carbohydrates, except that a measured quantity of bread is allowed for breakfast and lunch. The urine of the next twenty-four hours is collected, that of the day in a separate vessel from that of the night, and examined quantitatively for glucose, acetone, urea, and other ingredients. Both the percentage of sugar and the amount daily excreted are noted, and cases classified as slight, moderately severe, and grave, according to their degree of toleration. To the first class belong to those diabetics in whom the excretion of glucose is arrested on a starch free diet. To the second class, the moderately severe, belong those diabetics in whom the excretion of sugar is not completely arrested, but markedly diminished on a rigid starch free diet. To the third class, the grave cases, belong those diabetics in whom the excretion of glucose is not even diminished on a rigid starch free diet. In this last group of cases sugar is formed from the proteid food elements. The method used by the author for the toleration test is the following: On the first day three meals consisting entirely of proteids, fats, and water are given, but between breakfast and the

midday meal the patient is told to drink a mixture of 50 c.c. of glucose dissolved in 250 c.c. of water. The urine of the next twenty-four hours is examined quantitatively.

**3. The Relation of Appendicitis to Gynecological Pelvic Diseases.**—Bandler concludes that appendicitis in the form of an inflammation of the mucous membrane does not result from inflammatory diseases originating in the uterus or annexa. Involvement of the appendix viewed as a peritoneally covered organ may take place as part of a peritonitis, more or less localized or more or less extensive, which has its origin in inflammatory diseases of the annexa. Severe inflammations of the appendix, in so far as they cause a pelvic peritonitis or in so far as the accumulation of pus is located in the pelvis, naturally involve the uterus and annexa in adhesions, do not cause pyosalpinx, but may cause tuboovarian cysts. A distinctive diagnosis as to original site of the infection, when the appendix and right annexa are involved, is often impossible except from the operative clinical standpoint, and even then is not always certain. Mild attacks of appendicitis, without the production of well defined peritonitis, may involve the annexa without adhesions, but especially by infection of the Graffian follicles, alterations of the stroma and the production of varicocele of the broad ligament. Such alterations in the annexa generally result from processes extending from the cervix and uterus into the broad ligaments, and a definite decision as to the source of the trouble may be often impossible.

**4. Blood Pressure in the Practice of Medicine.**—Dutton says that in the study of abnormal blood pressure we have the underlying cause or sequence of over half the human ills, which makes it one of the most profound subjects known to the science of medicine. Much is understood and much is misunderstood. He thinks he has proved by his own experiments and observations that the life of the human organism, whether through heredity or other causes prone to be aberrated blood pressure, may be prolonged ten to twenty years. So long as normal blood pressure can be maintained, the life of the organism will be sustained until the natural sequences of decay result in death.

**6. The Solution of the Lodge and Society Problem of the East Side.**—Weiss speaks of the so called east side of New York City. He observes that the practice of medicine on the east side of New York is unique. Seventy-five per cent. is lodge and society practice. Three fourths of the physicians on the east side accept this kind of practice. The laity is organized, the physicians are disorganized. To gain contracts, physicians have to go through elections. To insure being elected, physicians make the worst concessions and lower their professional dignity. It is necessary for the physicians to cooperate to establish a uniform contract, and to raise the professional standard on the east side. To accomplish these reforms it is necessary to abolish the system of election and to establish the system of selection. To gain the good will and cooperation of the new and less successful practitioners, it is necessary that the old and more successful practitioners allow the

former to examine candidates of the various lodges and societies. There should be established offices where the examining physicians should be assigned in routine for the examination of candidates. The income from these candidates should be divided in equal shares quarterly among the examining physicians.

1. New Ideas on Fractures of the Utmost Importance to the Medical Profession and to the Lay Public in Connection with Their Responsibilities and Possible Legal Liabilities, By LUCAS-CHAMPIONNIÈRE.
2. Arthrodesis and Tendon Transplantation, By R. JONES.
3. The Most Ancient Splints, By G. E. SMITH.
4. The Post Mortem Staining of Bone Produced by the Ante Mortem Shedding of Blood, By F. W. JONES.
5. Examination of the Bodies of One Hundred Men Executed in Nubia in Roman Times, By F. W. JONES.
6. Remarks Upon Excision of the Body of the Scapula, with an Illustrative Case, By R. P. ROWLANDS.
7. Punch Fractures, By H. BURROWS.

**1. Fractures.**—Lucas-Championnière for thirty years has impressed the following precepts upon his students: 1. The accurate juxtaposition of the fractured extremities of bones, in order to reproduce the normal arrangement, is a laudable object. It is only achieved in a minimal number of cases. 2. Never tell a patient that you are going to obtain and that you have obtained this exact result. 3. The books teach you that this is the case, but clinically the statement is false, and it will turn against you in several ways. 4. The conditions that are necessary in order that a limb should again become functionally perfect are far from demanding this exact juxtaposition. There are a large number of conditions which are more essential, and which you should be more sure of satisfying. 5. Do not insist upon this claim. 6. Give no credence whatever to the statement that absolute lack of movement is the most favorable condition for the repair of bone and for the formation of callus. A certain amount of movement favors and accelerates bone formation. 7. Do not proclaim from the housetop that radiography gives you an exact picture of the fragments. But on the other hand never try to prevent the use of radiography for a bony lesion. Whenever it is materially possible to employ it, have it employed; but never allow it to be interpreted in your absence, and make a special point of explaining to the patient or his friends in the clearest possible way the interpretation of the photograph. The medical profession should make the lay public understand the difficulties involved in a study of fractures. They must know that (a) radiographs have to be interpreted; (b) the reduction of fractures is not an absolute rule and is often not indispensable; (c) absolute rest is not the necessary test of every sound treatment for fractures; (d) a fracture is not a simple lesion, but includes complications owing to displacement, and owing to rupture of tendons and muscles; and (e) there is no mathematical solution for the repair of fractures. It is always difficult to put the public on its guard against the rooted belief that it knows and can understand everything relating to medicine. But in the case of fractures the doctor must be especially on his guard, because nothing will uproot the conviction of the public that it can understand every

secret in connection with the treatment and repair of bones.

## 2. Arthrodesis and Tendon Transplantation.

—Jones points out the causes of failure and the essentials of success in the operations of arthrodesis and tendon transplantation. By arthrodesis we endeavor to ankylose a joint with the least possible sacrifice of bone. The joint thus fixed is usually perfectly healthy, but preternaturally mobile, and the muscles which should govern it are either wholly or partly paralyzed. The operation should be limited to those joints which are wholly dependent for their usefulness on outside appliances and which offer no opportunity for a successful tendon operation. The ankle joint is the one usually operated on, but it is of the utmost importance that it should not be fixed until we know: (a) That the paralysis is complete, and depends on the destruction and not on the temporary disorganization of motor cells. (b) That at least two years have elapsed in the case of muscles suspected to be completely paralyzed. (c) That apparently paralyzed but really over-stretched muscles have first undergone appropriate treatment. Failure of the operation is generally due to neglect of general principles. The operation should not be performed on children under eight years of age. It should not be performed until the surgeon is satisfied that the muscles are paralyzed beyond all hope. The preliminary preparation of the foot by wrench and tenotome must correct all deformity. The operation must be so planned that at its completion the bones lie in opposition to the foot, which should be placed in an overcorrected position. This is effected by the excision of skin flaps, by the shortening of lengthened tendons, and by the removal of graduated wedges of bone. The wedge should never be taken from the tibia lest the tibial epiphysis be injured. Splints should be applied and retained until union is complete. Tendon transplantation is indicated: (a) To fortify a weakened group of muscles. (b) To supplant a completely paralyzed muscle or group of muscles. (c) To obstruct an overacting spastic group. (d) To deviate tendon action when perverted—as in transference of the tendo Achillis to the outer side of the os calcis in congenital clubfoot to prevent inversion of the ankle. (e) As a help in partial arthrodesis. In tendon transplantation one must insist on: 1. The overcorrection of deformity as a preliminary act. 2. The removal of skin flaps to secure the uninterrupted continuity of the overcorrection. 3. The direct and not angular deflection of the tendon. 4. The free tunneling in one plane through the soft tissues. 5. The firm suturing into periosteum or bony groove. 6. The careful choice, tension, and nursing of the transplanted tendon. 7. The maintenance of a hypercorrected position until voluntary power is assumed to the tendon. 8. The deflection of body weight during walking from the remaining tendon.

6. **Excision of the Scapula.** Rowland's conclusions regarding excision of the body of the scapula are as follows: 1. For suitable cases excision of the body of the scapula, with preservation of the process and glenoid socket, is a much better operation than excision of the whole bone, because it leaves a fifth or more perfect from the functional

and the artistic points of view. 2. The operation is especially suitable for innocent growths, which fortunately and frequently leave the processes and the shoulder joint unaffected. 3. It may be adopted in preference to complete excision of the scapula for some small and slowly growing malignant growths without increasing the immediate risk of death, and probably without increasing the danger of either local or general recurrence. 4. It may be occasionally suitable for inflammatory diseases of the scapula when the shoulder joint is unaffected. 5. It is wise to tie the three main vessels as early as possible in the operation, and this can be easily done through a suitably arranged posterior T shaped incision. 6. The success of the operation largely depends upon careful asepsis, the sewing of some of the divided muscles together, and the early adoption of systematic active and passive movements of the shoulder.

8. Perforation of the Oesophagus by a Rabbit Bone: Septic Inflammation of the Mediastinum; Ulceration into the Aorta; Death from Hemorrhage. By R. L. KNAGGS.
9. The Method of Preparing "New Tuberculin" (Tuberculin T. R.) A Correction. By W. G. ROBERTS.

1. **Acid Intoxication.**—Bainbridge, in his Arris and Gale lecture on acid intoxication, draws at the outset a distinction between acidosis and acid intoxication. The essential feature of acidosis is the occurrence of certain abnormal acids in abnormal amount in the blood and the urine; the most important of these acids are lactic and betaoxybutyric acids, and their estimation in the urine furnishes the most accurate means of measuring the intensity of the acidosis. The term acid intoxication should be limited to conditions in which, in addition to acidosis, toxic symptoms referable to the organic acids make their appearance. Acidosis may be accompanied by diminution of the alkalinity of the blood, and the urinary excretion of ammonia is usually increased. Even in acidosis, however, the alkalinity of the blood remains remarkably constant, though it may be temporarily disturbed by a sudden production of acid, and a normal alkalinity of the blood may coexist with a considerable degree of acidosis. And neither the total excretion of ammonia in the urine nor the ammonia coefficient (i. e., the proportion of the total nitrogen excreted as ammonia) necessarily or even usually corresponds to the degree of the acidosis. Lactic acid is never the cause of acid intoxication in man, and

its appearance in the urine is either the result of excessive production by the muscles or is secondary to the failure of the liver to convert ammonia into urea; its occurrence is not due to deficient oxidation of lactic acid by the liver. It seems probable that in diabetes there is a gradual depletion of the alkalies in the tissues, and that a point is ultimately reached when the alkali content of the tissues is insufficient for normal metabolism and symptoms of intoxication occur. It is possible, of course, that the gradual loss of alkali simply lessens the amount of base available for the neutralization of acid, and that the ultimate result is an acid intoxication due to the diminished alkalinity of the tissues. It is also extremely probable that the lack of some or all of the inorganic bases may primarily disturb the course of the metabolism, quite independently of the alkalinity of the tissues, which last does not depend solely upon their inorganic constituents, since the proteins can apparently act either as weak acids or bases. On this view even the diminished alkalinity of the blood in coma may be interpreted as due to a final effort on the part of the tissues to satisfy their need for base. It is not sufficient to supply the body with sodium carbonate; the alkali treatment of diabetes might be of much greater value if all the bases required by the body were administered. Postanæsthetic acetoneuria is the common form in children. In most cases acetoneuria is the only symptom, but occasionally toxic symptoms develop, and death may ensue. The most characteristic symptoms are intense thirst, vomiting, restlessness, and finally coma; air hunger has been observed in some cases. Post mortem the liver shows constantly intense fatty infiltration, with patches of necrosis. The interest of postanæsthetic acetoneuria lies in the appearance of symptoms of acute intoxication in certain cases and in its relation to other forms of acetoneuria. The power of anæsthetics to interfere with metabolism as a whole and their toxic action upon protoplasm are well known. The metabolic disturbance is usually trivial, because the anæsthetic speedily leaves the tissue when the anæsthesia comes to an end. The severe toxic symptoms can only be explained by assuming that the anæsthetic remains in combination with certain tissues. If this be admitted, then the occurrence of acetoneuria is the inevitable outcome of the lessened oxidative capacity of the tissues. Postanæsthetic acetoneuria is closely analogous to phosphorus poisoning, in which the oxidative capacity of the tissues is primarily damaged. The inhibition of metabolism by anæsthetics results in the incomplete combustion of fat, and betaoxybutyric acid and its products appear in the urine, and the failure of the muscles to burn up fat leads to its accumulation in both the muscles and the liver. Fatty infiltration of the liver can occur with remarkable rapidity, and there seems to be no reason to believe that when symptoms of intoxication occur after anæsthesia the liver was previously diseased. Patients who take carbohydrate freely both before and after operation seem less liable to acetoneuria, and it is probable that postanæsthetic acetoneuria may sometimes arise solely from carbohydrate starvation, especially in those cases in which, owing to vomiting, but little food has been taken previous to operation.

## LA PRESSE MEDICALE

March 21, 1908.

1. Anaphylaxia, By Professor CH. RICHET.
2. Appendicitis and Chronic Ulcer of the Stomach, By R. ROMME.

1. **Anaphylaxia.**—Richtet applied this term in 1902 to a phenomenon he had discovered while studying the action of certain poisons, namely, the sensibility of the organism to a second injection of a poison after recovery from the effects of the first injection and apparently total elimination of the toxic substance. The sensibility of the organism to the second dose as compared with its sensibility to the first may be either less, equal, or greater. The author considers that anaphylaxia merits careful study from the point of view of pathology and general therapeutics, because he believes that through it may be found an explanation of the peculiar phenomenon called idiosyncrasy, which is the difference of reaction in different individuals.

March 25, 1908.

1. The Course to Be Pursued in the Treatment of a Complicated Fracture, By P. HARDOUIN.
2. Disassociation and Antagonism of the Cutaneous and Tendonous Reflexes, By NOICA.

1. **Treatment of Complicated Fractures.**—Hardouin gives, as the proper course to be pursued in the treatment of a complicated fracture, cleansing of the skin, an incision, or an enlargement of the external wound sufficient to obtain enough space for the necessary manipulation, usually from four to six centimetres long, resection of the parts of the bone that should be removed, cleansing of the wound, drainage, and the application of a dressing.

## LA SEMAINE MEDICALE

March 25, 1908.

Periphere Rheumatismal Arteritis,

By M. ROCH and R. BURNAND.

**Periphere Rheumatismal Arteritis.**—Roch and Burnand report a case of rheumatism followed by pain in certain parts of the limbs associated with loss of pulse, which they are inclined to ascribe to a local arteritis for the following reasons: 1, The progressive onset of the pain, which was preceded by tingling and a feeling of weight in the limb, that required two days to reach its maximum. 2, The attacks of fever, which each time preceded the appearance of the arterial pains, which can be explained by nothing else than an infection. 3, The nodulæ of early periarteritis with painful oedematous infiltration along the course of the artery for a considerable extent seems to accord with the idea of an arteritis involving all the coats of the vessel rather than with the idea of a mechanical obstruction by means of an embolus. 4, The transitory character of the obliteration on the part of the artery most affected. 5, The fact that the radial pulse was at first wholly suppressed and that when pulsation returned it was manifest during compression of the artery above the pulse showed a temporary obliteration of the vessel throughout its length and not merely an obliteration limited to a segment at its upper extremity. 6, It has been noted that in the phase just before obliteration in endarteritis the pulse of the affected artery is stronger than that of the corresponding artery. In this case it was noted just before the onset of the symptoms that the pulse of the left radial artery, which later was obliterated,

was stronger than that of the right. The only objections are that there was a cardiac lesion present which might account for embolism, and that the infection must be ascribed to the rheumatismal virus.

#### BERLINER KLINISCHE WOCHENSCHRIFT

March 16, 1908.

1. Concerning the Indications for Radical Operation in Inflammatory Diseases of the Accessory Sinuses of the Nose, By A. KUTTNER.
2. Operation for Acute Hæmorrhage from the Pancreas, By F. BREWITT.
3. The Wave of the Phlebogram, By D. PLETNEW.
4. The After Treatment of Carcinoma that Had Been Operated on with Homogeneous Irradiation, By FRIEDRICH DESSAUER and MAX KRÜGER.
5. Concerning the Infectious Origin of Chronic Pancreatitis and Diabetes, By FELIX HIRSCHFELD.
6. Studies of the Secretion of Pepsin in Healthy and Diseased Infants, By J. ROSENSTERN.
7. The Cutaneous and Conjunctival Reaction to Tuberculin in Animals, By HANS WILDBOLZ.
8. Concerning the Value of Pirquet's and Wolff-Calmette's Reactions in Childhood, By ROBERT BING.
9. The Therapeutic Use of Radium Emanations, By FRANZ NAGELSCHMIDT.
10. Concerning Puerperal Fever, By ERNST RUNGE.

1. **Radical Operation in Diseases of the Accessory Sinuses of the Nose.**—Kuttner protests against too ready adoption of surgical measures in diseases of the accessory sinuses, because daily experience shows that the chances of recovery without such intervention are much greater in both acute and chronic forms than could theoretically be expected. Intranasal treatment should be adopted in all cases in which serious complications are wanting.

2. **Operation for Acute Hæmorrhage from the Pancreas.**—Brewitt reports a case of hæmorrhage from the pancreas in a boy, sixteen years old. He was seized twice within twenty-four hours with severe abdominal pain, nausea, and vomiting. The localization of the first appearance of the pain could not be determined. Laparotomy was performed, the pancreas found to be enlarged with a swelling as large as an apple in its middle, that was found to contain a bloody serous fluid. This was incised and drained, the abdomen washed out with salt solution, and the patient made a good recovery. But for the operation the condition would in all probability have proved fatal.

4. **After Treatment of Carcinoma that Had Been Operated on by Irradiation.**—Dessauer and Krüger say they obtain a deep reaction in inoperable carcinomata treated with homogeneous irradiation for a long time, but do not go so far as to say that the x rays can destroy all large tumors in the body without injury to the organism. They fear not burns of the skin, but a weakening of the body by the formation of toxins as the result of the breaking down of tissue. As much as possible of the malignant tumor should be removed by the hand of the surgeon. As an after treatment directly following the operation the use of the x rays is of great value and makes it possible to prevent a recurrence.

8. **Value of Pirquet's and Wolff-Calmette's Reactions in Childhood.**—Bing reviews these tests and concludes that Pirquet's cutaneous test is absolutely without danger, while the same can-

not be said of the conjunctival reaction. Pirquet's test also reveals latent tuberculosis, while a negative conjunctival reaction does not exclude it.

9. **Therapeutic Use of Radium Emanations.**—Nagelschmidt reports ten cases in which he has successfully employed radioactive water. The diseases thus treated include articular rheumatism, ozæna, crepitation of the scapula, muscular rheumatism, and chronic catarrh of the bladder.

#### MÜNCHENER MEDIZINISCHE WOCHENSCHRIFT

March 24, 1908.

3. The Actual Changes in Operative Obstetrics, By BAISCH.
4. Concerning Localization and Clinical Symptoms of Intracranial Extravasations of Blood in the Newly Born, By SEITZ.
5. Stasis Hyperæmia in Acute Inflammatory Diseases, By COSTE.
6. Concerning the Connection Between Diseases of the Stomach and of the Nose, By HECHT.
7. The Treatment of Malaria with Atoxyl, By GEORGOPULOS.
8. Concerning Three Rare Forms of Hæmorrhage During Delivery, together with Some Remarks on the Preparation of Students for the Treatment of Puerperal Hæmorrhages, By SELLEIM.
9. Temperatures of Opposite Sides of the Body in Appendicitis, By WIDMER.
10. Concerning Diabetes and Psychosis, By KAUFMANN.
11. Concerning the Life Saving Action of Infusions of Adrenalin and Salt Solution in a Case of Peritoneal Sepsis, By ROTHSCILD.
12. A Case of True Cholesteatoma of the Ear, By HANSEN.
13. Concerning a Phlegmon of the Neck of Dental Origin Which Presented the Clinical Picture of Angina Ludovici and was Associated with a Retropharyngeal Abscess, By TRAUTMANN.
14. The Postoperative Tetanus Cases of Zacharias, Cases of Catgut Tetanus, By KUHN.
15. The Genesis of Gallstones, By LICHTWITZ.
16. Obituary of Nicholas Senn, By ALLEMAN.

1. **Theory of the Natural Immunity of Living Tissue.**—Holzinger declares that a certain weak degree of osmotic movement in a nutritive solution restricts the growth of microorganisms, which grow luxuriously in the same solutions when at rest, and that with a greater degree of intensity of the osmotic movement of a nutritive solution, which in a state of rest furnishes good material for the proliferation of microorganisms, will completely check such proliferation. Hence he advances the theory that the living tissue is immune because the osmotic processes in the tissue prevent the development of microorganisms that penetrate into it. It is only when there is a marked slackening of these processes and a relative rest of the tissue fluids that these become favorable nutritive material and render infection possible.

4. **Localization and Clinical Symptoms of Intracranial Extravasations of Blood in the Newly Born.**—Seitz has observed twenty-three cases of intracranial hæmorrhage in the newly born, eighteen of which were fatal. These he examined pathologically by means of frozen sections, and found that these hæmorrhages, instead of being arterial as is usual in adults, were venous almost without exception, that they were almost always subdural between

the dura and the pia, almost never in the brain substance, and rarely in the ventricles. Hematomata between the dura and the bone are rare, not extensive because of the firm adherence of the dura to the bone, and never cause symptoms of pressure on the brain. The point of greatest clinical importance is whether the hemorrhages are infratentorial, over the cerebellum and medulla, or supratentorial, over the cerebrum. The infratentorial hemorrhages are particularly dangerous, and, so far as his observation goes, are always fatal. They come from small lacerated veins which open into the transverse or neighboring sinuses. The amount of blood is usually slight, little if any over a teaspoonful. When the transverse itself is lacerated the hemorrhage is much greater and death is immediate. The danger from these little hemorrhages in this place is due to the pressure on the medulla oblongata and the centre of respiration. Only blood stained fluid, no pure blood, can be obtained by lumbar puncture. The symptoms of an infratentorial hemorrhage are said to be typical, so that a diagnosis may be made with tolerable certainty during life. The children are born either slightly or not at all asphyxiated, cry strongly and give the impression at first of perfectly healthy children. After some hours symptoms referable to the medulla oblongata appear, irregular, choppy, accelerated respiration, occasionally marked respiratory spasms with deep cyanosis. In the meantime the skin has assumed a bluish yellow pallor, and the tension of the large fontanelle is greatly increased. The breathing grows worse or the respiratory spasms become more frequent, until death occurs from twenty-four to forty-eight hours after birth. When death is somewhat longer delayed some cerebral symptoms may develop from the setting back of the blood, and if the hemorrhage takes place more in the spinal canal certain spinal symptoms will be present. Supratentorial hemorrhages are almost always unilateral and situated over the convexity of the brain. The quantity of blood is usually greater, so that more pressure is exerted upon the neighboring parts of the brain. The blood comes from lacerated veins that empty into the longitudinal sinus. The children may be born spontaneously, easily, and quickly of multipara, or they may be forceps cases. They are not asphyxiated, or revive with little difficulty and cry well. During the first day nothing wrong is to be noted; on the second day they become very restless, cry continually, and refuse to nurse. This hard crying apparently without reason is a very characteristic symptom, and in the author's experience is always present. It is caused by the painful tearing of the dura. The great fontanelle shows about this time a somewhat increased tension, and the following symptoms gradually develop, dependent on the pressure on the brain: Disturbances of respiration, especially spasms during inspiration, increase of the blood pressure, unconsciousness, and sometimes, though not as commonly as in adults, slowing of the pulse, from irritation of the vagus. The chalky white appearance of the children is very marked. In addition to these general symptoms there are local symptoms from which the seat of the hemorrhage can be determined in some cases. In all cases with marked progressive symptoms of intracranial pressure, operative inter-

vention is indicated, which has been practised sometimes with success. The five children that recovered were cases of cerebral hemorrhage. Three recovered fully and later showed no trace of mental or nervous disturbance. The fourth had nystagmus, strabismus, and athetosis of the left hand. He died when nine months old of gastroenteritis. Of the fifth nothing certain could be learned.

## Proceedings of Societies.

### AMERICAN SOCIETY OF TROPICAL MEDICINE.

*Fifth Annual Meeting, Held in Baltimore on March 28, 1908.*

The President, Dr. JAMES M. ANDERS, of Philadelphia, in the Chair.

**A Review of the Year's Progress in Tropical Medicine** was the title of the president's address. He referred to the work of the Indian Plague Commission, which has resulted in the confirmation of the suspicion that plague was transmitted from rat to rat and from rat to man by the rat flea (*Pulex cheopis*). He referred to the results of the use of Haffkine's prophylactic in reducing the mortality by about eighty-five per cent. He mentioned the work of Strong in his attempt to produce artificial immunity by the injection of attenuated living cultures of *Bacillus pestis*. He spoke of the work of Ashburn and Craig on the relation of *Culex fatigans* to the distribution of *Filaria philippinensis*, and on the development of the embryos of this nematode worm in the mosquito in question. He also referred to the work of the same authors on the transmission of dengue by the same mosquito, *Culex fatigans*. The paper by Musgrave on paragonimus infection, the discovery of a body resembling a spirochæta in a kidney from a case of yellow fever, the theory of the ætiology of beriberi advanced by Hewlett and DeKorte, with the description of a protozoon parasite; the treatment of Malta fever with a bacterial vaccine prepared from pure cultures of *Micrococcus melitensis*; the occurrence of *Entamaba coli* in the stools of apparently healthy men; the comparative study of dysenterylike bacilli by Fisher; the reports of cases of gangosa by Stitt and by Musgrave and Marshall in the Philippines; the work on human myiasis; the work of the Puerto Rico anemia commission on uncinariasis and their good results during 1906, when they treated more than 89,000 cases; the International Conference on Sleeping Sickness and Koch's suggestion that the disease might be transmitted by coitus; the formation of the International Society of Tropical Medicine at the Fourteenth International Congress of Hygiene and Demography; the establishment of the *Annals of Tropical Medicine and Parasitology* and of the *United States Naval Medical Bulletin*, were all referred to.

Dr. JOHN M. SWAN, of Philadelphia, read the report of the secretary and the report of the treasurer.

**A Memoir of the Late Dr. James Carroll** was

read by Dr. JOSEPH MCFARLAND, of Philadelphia, an honorary member of the society.

Dr. WILLIAM S. THAYER, of Baltimore, described the last illness of Dr. Carroll.

**Soil Pollution in Hookworm Disease** was the title of a paper by Dr. CHARLES WARDELL STILES, of the United States Public Health and Marine Hospital Service. Dry skin, dry hair, winged scapulæ, and tibial ulcers were constant phenomena in cases of hookworm infection. Dr. Stiles was of the opinion that the worm was a blood sucker, and said that if the worm was examined as soon as it was expelled, blood would be found in its gastrointestinal tract. Hookworm disease was more frequent in a country in which there was sandy soil than in one in which the soil was composed of clay, as illustrated in some of the southern United States. The number of cases of infection rose in districts in which there was a sandy soil, and fell in districts in which there was a clay soil. Soil pollution was the great cause for the spread of the disease. The small farms were not provided with proper privies, so that the result was a large amount of soil pollution. Dr. Stiles was of the opinion that the poor white in the South was the product of hookworm disease to a great extent. He showed a plan for a hygienic privy for small farms.

Dr. WILLIAM S. THAYER, of Baltimore, asked what could be accomplished by having the people wear shoes.

Dr. STILES said that many of the people in the rural districts of the South could not afford to buy shoes. Eighty per cent. of the cases were preceded by ground itch, but he was of the opinion that the educated people were infected through the mouth.

Dr. BAILEY K. ASHFORD, of the army, said that, so far as Puerto Rico was concerned, there was no distinction of frequency of infection as regarded the soil. In that island the infection was so prevalent and the conditions were so favorable for the development of the embryos that the character of the soil made no difference. He had seen cases of tibial ulcers which recovered following the use of thymol. He gave it as his opinion that the symptoms of uncinariasis were due to the liberation of a hæmolytic toxine. Dr. STILES said that the population of Puerto Rico was seven times as dense as that of North Carolina, for example, and that the chance for soil pollution and infection was much greater.

**Rat Extermination** was the title of a paper by Mr. D. E. LANSZ, of the United States Department of Agriculture. He said there were some 300 species of rats in the world, but there were only four species which were cosmopolitan—*Mus rattus*, the black rat; *Mus decumanus*, the gray rat; *Mus alexandrinus*, the roof rat; and *Mus musculus*, the mouse. Ninety-eight per cent. of the rats in the United States were of the species *Mus decumanus*, and about two per cent. were of *Mus rattus*. *Mus decumanus* was adaptable to all kinds of temperatures; it even lived in cold storage plants; the female had from three to five pregnancies a year, with an average of ten young at each pregnancy in the latitude of Baltimore; in the South the number in

each litter was less; in India there was an average of 8.1 to each litter. The fecundity of the rat was increased by a plentiful supply of food. *Mus decumanus* was the most destructive rodent in the world. If each farmer in the United States had one rat for every head of live stock on his place, the grain bill would be \$100,000,000 yearly. *Mus decumanus* was omnivorous; it carried plague, and disseminated trichiniasis and septic pneumonia. The latter disease he believed was often due to drinking water in which a rat had died and in which its body had decomposed. In San Francisco the sanitary authorities were catching 10,000 rats a week and expending about \$42,000 a week. About one per cent. of these rats were infected with *Bacillus pestis*. In order to exterminate rats their natural enemies must be spared—hawks, owls, and skunks. The injury done by these animals to game was not nearly so great as that done by the rats. Buildings might be kept free from rats by employing rat proof construction and by screening low windows. The guillotine trap was the best device for the destruction of the animals; the best bait was "wienerwurst." Poisons could not be placed about inhabited buildings.

**Puerto Rico as a Field for Research in Tropical Medicine.**—Dr. ASHFORD read a paper on this subject. He had seen about 15,000 patients in hospitals and dispensaries while on duty in the island, and he supposed that at least 20,000 others had been seen by his colleagues. Uncinariasis was by far the most important disease. Seven per cent. of the strength of one battalion harbored *Filaria nocturna*. Chyluria, varicose groin glands, and other filarial diseases were common. Erysipelas bore a relation to filarial disease, particularly when in the lower limb; it was sometimes confounded with malarial disease. Bilharziosis was fairly common; in one district five per cent. of the rural population were infected with *Schistosomum Mansoni*. This infection was not attended by eosinophilia. The ova were never found in the urine. The infection seemed to be on the increase, and in places it was epidemic. The most common symptoms were bloody and mucous stools with pain. Ascariis and oxyuris infections were common. In one case of the latter infection 418 worms were expelled after two doses of beta naphthol of two drachms each. Strongyloides and *Trichocephalus trichiuris* infections were common; cestodes were rare; trematodes offered a fertile field for original work. Abscess of the liver was very rare; amœbic dysentery was, consequently, not common; there was no kala azar and no trypanosomiasis. *Treponema pertenue* must exist, although the speaker had seen no cases of yaws. Malaria was common in certain valleys and coast districts. Typhoid fever was very fatal and was becoming a cause for alarm. Puerto Rico offered a favorable opportunity for the use of anti-plasmodium. Bacillary dysentery was not common at present, although it might be epidemic at times. There was no plague, no cholera, no yellow fever, and no Malta fever. There was some typhus, an occasional case of glanders, tetanus in infancy, and sprue occasionally. Trichinosis was met in the towns, but not in the mountains; beriberi might be confirmed with accuracy. There had been a great change in the

attitude of the people toward hygienic methods since the successful work of the anæmia commission.

Dr. STILES said that he had seen endemic cases of bilharziosis in Florida. He was of the opinion that the disease was much more common in this country than was usually thought to be the case. He was coming to believe that the separation of *Schistosomum Mansoni* from *Schistosomum hæmatobium* was justifiable. The fasciola found in Puerto Rico was a new species. He said that the ordinary treatment of oxyuris infection was wrong. The adult worms lived in the small intestine and should be driven into the large intestine by an anthelmintic before local injections were given.

Dr. JOHN M. SWAN, of Philadelphia, said that within the last month, through the kindness of Dr. A. A. Eshner, he had had the opportunity of examining the blood of a stout African negro in whom there was an infection with *Schistosomum Mansoni*. The blood had shown only 4.2 per cent. of eosinophile cells. He said that he had succeeded on one occasion in expelling four adult specimens of *Trichocephalus trichiuris*, two males and two females, with thymol, used as advised by the Puerto Rico anæmia commission.

Dr. JUDSON DALAND, of Philadelphia, said that kala azar might in the future be imported into the West Indies by the coolie laborers from India.

**Vaccination Against Plague.**—Dr. C. P. EMERSON, of Baltimore, read this paper, by Dr. RICHARD P. STRONG, of Manila. He described the treatment of persons exposed to plague by the injection of attenuated living cultures of the *Bacillus pestis*. He had vaccinated 200 persons. There was no severe reaction. There was a little induration and redness, with soreness on pressure, at the point of inoculation. There had been no serious results so far. The examination of tissues from apes after the inoculations showed the presence of the organisms in the tissues. The bacilli evidently reproduced for a time and then died off. Vaccination should be done only when the operator could guarantee the organism to have lost all virulence. The stability of the virulence of the *Bacillus pestis* necessitated the greatest precautions and repeated testing on guinea pigs. A higher degree of immunity was obtained by this method than by any other.

Dr. WILLIAM H. WELCH, of Baltimore, said that there was no instance of substantial protection from disease by the injection of killed organisms. It was only by the injection of living cultures that we could expect to get the best results in protective vaccination. The vaccination against smallpox, anthrax, rinderpest, and tuberculosis in cattle was all done with living organisms. There seemed to be little hope in the direction of vaccination with killed organisms.

**Quinine Prophylaxis and Mechanical Prophylaxis of Malaria.**—Dr. WILLIAM S. THAYER, of Baltimore, read this paper. Malarial prophylaxis by mechanical appliances included the protection of human beings from the bites of mosquitoes by screening, burning pyrethrum powder in the houses daily, and wearing protective articles of clothing on the head and hands while out of doors. These methods had been carried out best by the Italians, both officially and through the efforts of private corpora-

tions. On the railways which ran through very malarial districts, and on which these methods had been employed, the incidence of the disease had been much reduced. The method was expensive, troublesome, and often impracticable. The Italians had done much work in the destruction of the malarial parasite within the human host by the prophylactic use of quinine. The spring relapses initiated the regular malarial season. In every relapse, according to certain methods of treatment, the patient received one or two grammes of quinine daily until the infection was eradicated. Then he received one gramme every eighth or ninth day for two months.

There were many objections to this method of treatment—that the patient forgot it was not the least of these. Consequently, instead of this routine the patients were treated vigorously until the infection was conquered, and then small doses of quinine, six grains daily, were given for a prolonged period. Also all the inhabitants of a malarial district received this prophylactic dose of quinine, two grains three times a day, throughout the malarial season. The results of continuous treatment were much better than those of intermittent treatment. The difficulties in the way of the general adoption of this form of treatment were the expense of the method and the lack of appreciation of its value on the part of the public. In order to adopt a system of quinine prophylaxis, furthermore, it was necessary to furnish the drug in a form not too unpleasant for both adults and children. In Italy the government sold quinine bisulphate or quinine dihydrochloride in sugar coated tablets for adults, and as quinine tannate made into a confection with chocolate for children. These forms were readily absorbed, and the children took the latter form of the drug readily. The tannate confections were supplied by a private corporation, because there is a member of the Italian government who believes that quinine tannate was not readily absorbed. Dr. Thayer exhibited tables which showed that under this system of quinine prophylaxis there was less malarial disease in Italy than formerly, even in intensely malarial districts, and which also showed that the death rate was much less. The state made a profit on the sale of the quinine. If the state would take up the sale of quinine tannate for the children, the results would be better than they were now. In the malarial districts of the United States there was need of cooperation of the municipal, county, State, and national governments to establish some such system. In addition, the cooperation of local boards of health and medical societies was required to educate the public to the necessity for the adoption and continuation of such a measure. The physician should be educated in the modern methods of combating and recognizing the disease, and an efficient and agreeable form of quinine should be offered for sale at a low rate.

**Mosquito Extermination.**—Dr. L. O. HOWARD, of the Department of Agriculture, read a paper on this subject. He said that the Italian method of prophylaxis was by giving quinine; the German method was to prevent the mosquito from biting the infected individual; but the American method was to destroy the breeding places of the mosquitoes. He pointed out some of the fallacies that had so far been discovered in the methods of working out the

problem, and showed the necessity for studying the habits of the insects and for discovering the varieties of mosquitoes that were able to transmit the disease. He said that mosquitoes would breed in salt water, in the bilge water in vessels, in holes in the trunks of trees, and in other out of the way places. He exhibited a number of lantern slides showing mosquito breeding places and the methods adopted in various parts of the United States to destroy these breeding places.

**A Tank in which Live Mosquito Larvæ and Pupæ Might be Exhibited**, by being thrown on the screen by an ordinary projection apparatus, was shown by Dr. WILLIAM N. HILL, of Baltimore.

Dr. EDWARD R. STITT, of the navy, called attention to the difficulties of drainage in the tropics, and to the difficulties in inducing persons to use mosquito net constantly, on account of the climatic peculiarities. In places in the Philippines it was necessary to use oil after burning off the tropical undergrowth. Tadpoles were of use in destroying larvæ, and their development should be encouraged in places in which mosquitoes bred. When he was serving as the medical officer of the Nicaragua Canal Commission, he was told by a physician who had had much experience in the tropics that quinine prophylaxis was unsatisfactory, and that when persons who had taken prophylactic doses of quinine became infected their attacks were harder to cure, and that relapses were more common and were difficult to cure. He spoke of two instances which seemed to show that the malarial parasite could acquire a resistance to quinine.

Dr. W. E. ROBERTSON, of Philadelphia, said that he had seen twenty cases of malarial disease which were contracted in Colon, in which the patients had received quinine prophylactically. In these cases it was difficult to demonstrate the organism, and it was only after the use of quinine hypodermatically that a cure was obtained. One of the patients had gangrene of the skin after this form of treatment, and another had a severe attack of multiple neuritis.

Dr. STILES said that we ought to say protection against mosquitoes and not mosquito extermination in speaking of malaria prophylaxis. The doctrine of mosquito extermination was doing harm, because it was such an expensive procedure that communities were staggered when they considered the necessary outlay. Mosquito extermination, for this reason, was not practicable in many districts in the South. In these districts, however, it was possible to protect against mosquitoes.

Dr. HILL said that it was practicable to eradicate mosquitoes. It was an economic question. Drainage of land worth little increased its value several hundred times. It required the cooperation of the town, county, State, and national governments.

Dr. WILLEN thought that probably the chances of infection might be diminished by taking quinine.

Dr. HAMILTON WRIGHT, of Washington, said that he had been in charge of sanitary measures for the eradication of malaria at Port Swettenham, Federated Malay States. Every form of prophylaxis known was adopted, and in six weeks there was no malaria in the port. This result was accomplished at a cost of \$50,000.

Dr. THAYER said that it was advisable to employ

every prophylactic measure. Quinine should be used for at least a month after the malarial paroxysms had ceased. It was well known that relapses were less tractable than the original attacks. He did not think that the previous administration of prophylactic doses of quinine lessened the number of parasites in the peripheral blood in cases of fresh infection.

**Strongyloides Intestinalis in Philadelphia.**—Dr. DALAND read this paper. He reported a case of infection originating in a Philadelphian who had spent six days in Mexico six years before. The history of the case seemed to exclude water infection. The blood of this patient contained from 38.2 to 27 per cent. of eosinophile cells. The reduction in the number of eosinophile cells was coincident with improvement in the symptoms of the infection. The author described experiments made with the feces of the patient, in which he succeeded in developing both male and female adults from proper culture materials, and from which he succeeded in infecting guinea pigs by the application of the feces to a shaved area of the abdomen. The tail of the male worm was supplied with a bursa, and there were some other anatomical features which seemed to show that the parasite was a new species.

Dr. STILES brought some theoretical objections to the acceptance of this as a new parasite, the chief of which was that the earth and water used in making the cultures had not been sterilized.

Dr. THAYER said that the frequency of the occurrence of ova in the stools of the patient and the presence of such a high eosinophilia seemed to show some differences from the ordinary strongyloides infection.

Dr. DALAND said that ova in which embryos were about to escape were common in the stools at the present time.

Dr. ALLEN J. SMITH had reported to Dr. Daland that the parasite seemed to be a new species.

**The Comparative Morphology of the Spirochætæ of Syphilis and Yaws.**—Dr. F. F. RUSSELL, of the army, read a paper thus entitled. The author said that there appeared to be differences in morphology which were regular and constant, and that the species were distinct.

The society then adjourned to the Laboratory of Chemical Pathology, where Dr. TERRY, of New York, gave a demonstration of living spirochætæ and trypanosomes.

The following papers were read by title: Report of the Society's Representative at the Third International Sanitary Convention of American Republics, Dr. R. H. von Ezdorf, of the Public Health and Marine Hospital Service; Twenty Years' Experience with the Hypodermic Use of Quinine and Urea Hydrochloride in Malarial Infection, with Remarks on the Thirteen to Fourteen Days' Cycle of Freedom Produced by a Single Injection, by Dr. S. Solis Cohen, of Philadelphia; A Biographical Note of Dr. Louis Eschscholtz, by Dr. Aristides Agramonte, of Havana; Some Notes on a Collection of Larvæ Made by Dr. F. C. Reddick, Wellman in Portuguese West Africa, by Dr. Henry B. Ward, of Lincoln, Nebraska; The Pathogenesis of Pernicious Malaria, by Dr. William H. Deader-

ick, of Marianna, Arkansas; Clinical Charts of Quartan Malarial Fever Observed in the West Africa, with Commentary, by Dr. F. Creighton Wellman, of Benguella, Angola, West Africa; History of a Case of Malarial Fever, Algid Form, Choleraic Type, by Dr. R. H. von Ezdorf; The Prevention of Tropical Abscess of the Liver by the Early Diagnosis and Treatment of the Presuppurative Stage of Amœbic Hepatitis, by Dr. Leonard Rogers, of Bombay; and A Review of the Recent Work on Spirillar Fevers, by Dr. F. Percival Mackie, of Bombay.

Officers for the Ensuing Year were elected as follows: President, Dr. James M. Anders, of Philadelphia; vice presidents, Dr. William S. Thayer, of Baltimore, and Dr. Rudolph Matas, of New Orleans; treasurer, Dr. Wharton Sinkler, of Philadelphia; secretary, Dr. John M. Swan, of Philadelphia; assistant secretary, Dr. Edward R. Stitt, of the navy; councillors, to serve for two years, Dr. George Dock, of Ann Arbor, Mich., and Dr. Joseph McFarland and Dr. Judson Daland, of Philadelphia.

### Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

*The Production and Handling of Clean Milk.* By KENELM WINSLOW, M. D., M. D. V., B. A. S. (Harv.), Formerly Instructor in Bussey Agricultural Institute and Assistant Professor in the Veterinary School of Harvard University, etc. New York: William R. Jenkins Company, 1907. Pp. 207. (Price, \$2.50.)

A glance at the title page indicates clearly the author's qualifications for the work he has undertaken, and the finished product of his mind often bears ample testimony to Dr. Winslow's fitness for the task. There are three introductory chapters devoted to Germs in their General Relation to Milk; Composition of Milk and Cream and Their Products; and Milk Products; then four—Feeding for Milk; Housing and Care of Cows; Handling of Milk and Cream; Cost of Producing and Distributing Clean Milk. Chapters viii and ix are devoted to milk distribution and inspection. These are followed by an appendix relating to the construction of barns and milk houses and their proper maintenance and care; and lastly we find a general outline of a scheme for the control, supervision, and inspection of a city milk supply.

We have rarely laid down a book the perusal of which has given us so much pleasure. It is simple, instructive, and practical, and the physician who masters its contents will be in a position to influence the dairy farmer in his rural surroundings greatly and aid the general present movement in the effort to secure clean milk at its point of production. The work is well illustrated with cuts of improved dairy apparatus, etc.

We have but one fault to find—the price seems too high. Two dollars would have been ample, and would, we think, lead to a much larger sale, and correspondingly increase its influence in the community.

*Medical Lectures and Aphorisms.* By SAMUEL GEE, M. D., Fellow of the Royal College of Physicians, Honorary Physician to H. R. H. the Prince of Wales, and Consulting Physician to St. Bartholomew's Hospital. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1908. Pp. viii-308.

"Samuel Gee" we read on the title page, and "S. J. Gee" and "Samuel Jones Gee" on the cover. Dr. Gee, whatever his full name may be, has given us a charming little book. It is not one to which the practitioner will resort to "read up," but it is one which the scholarly physician may pick up at any time, and, opening it at almost any page, find profitable and entertaining reading.

Our author is evidently a man of erudition, and his style is somewhat suggestive of the late Sir Thomas Watson's, though he has not Watson's elegance of diction. He is inclined to be aphoristic, and this tendency occasionally leads him to make statements that it might be difficult to prove. For example (on page 15) he says: "Apoplexy signifies deep coma coming on suddenly and lasting till death." Of course, the coma does not last till death in cases of recovery, however temporary and incomplete, from an apoplectic stroke.

Dr. Gee's reasoning is always consonant with plausibility, though it is not invariably convincing. One of the best examples in the book is to be found in his lecture on the nature of asthma (page 129). Almost the whole of the book is good, and we advise our readers to obtain it. If they once begin to read it they will hardly let it alone till they have finished it. The present edition is the third, though it is not so stated on the title page.

*The Semiinsane and the Semiresponsible* (Demifous et Demiresponsables). By JOSEPH GRASSET, Professor of Clinical Medicine at the University of Montpellier, etc. Authorized American Edition, Translated by SMITH ELY JELLIFFE, M. D., Ph. D., Clinical Professor of Mental Diseases Fordham University, New York. New York and London: Funk & Wagnalls Company, 1907. Pp. xxv-415.

Dr. Grasset remarks in his preface: "Society knows to-day that, if it has any rights in connection with criminals, it has also duties toward the diseased. And, further, in the presence of a misdemeanor or a crime it ought to put the question, Should the accused be punished or should he be treated?" To this the author gives his answer, which he demonstrates in his book thus: The accused may be entirely responsible, and ought to be punished; or he is entirely irresponsible, and ought to be treated; or he has an attenuated responsibility, and ought to be first placed in prison and later in a hospital.

This third group, that of the borderland type, is the main subject of the book, and the author comes to the conclusion that the semiinsane and the semiresponsible have rights which should be taken into consideration, legally as well as scientifically. They are described as they appear in literature, on the stage, and in history, and as they are met in daily practice by the specialist. We find among them persons of genius who have been of great benefit to mankind, and, again, persons whose actions have been of great detriment and danger to their fellow men.

The book has been well translated and will certainly find a ready audience among physicians, jurists, and laymen.

grade of first lieutenant in said corps shall be subject to examination as hereinafter provided: Provided, That the increase in grades of colonel, lieutenant colonel, and major provided for in this act shall be filled by promotion each calendar year of not exceeding two lieutenant colonels to be colonels, three majors to be lieutenant colonels, fourteen captains to be majors, and of the increase in the grade of first lieutenant of not more than twenty-five per centum of the total of such increase shall be appointed in any one calendar year: Provided further, That those assistant surgeons who at the time of the approval of this act shall have attained their captaincy by reason of service in the volunteer forces under the provisions of the Act of February 2, 1901, Section 18, or who will receive their captaincy upon the approval of this act by virtue of such service, shall take rank among the officers in or subsequently promoted to that grade, according to date of entrance into the Medical department of the Army as commissioned officers.

Section 4. That no person shall receive an appointment as first lieutenant in the Medical Corps unless he shall have been examined and approved by an Army medical board consisting of not less than three officers of the Medical Corps, designated by the Secretary of War.

Section 5. That no officers of the Medical Corps below the rank of lieutenant colonel shall be promoted therein until he shall have successfully passed an examination before an Army medical board consisting of not less than three officers of the Medical Corps, to be designated by the Secretary of War and to be held at such time anterior to the accruing of the right to promotion as may be for the best interest of the Service: Provided, That should any officer of the Medical Corps fail in his physical examination and be found incapacitated for service by reason of physical disability contracted in the line of duty, he shall be retired with the rank to which his seniority entitled him to be promoted; but if he should be found disqualified for promotion for any other reason, a second examination shall not be allowed, but the Secretary of War shall appoint a board of review to consist of three officers of the Medical Corps superior in rank to the officer examined, none of whom shall have served as a member of the board which examined him. If the unfavorable finding of the examining board is concurred in by the board of review, the officer reported disqualified for promotion shall, if a first lieutenant or captain, be honorably discharged from the Service with one year's pay; and, if a major or lieutenant colonel, shall be debarrd from promotion and the officer next in rank found qualified shall be promoted to the vacancy. If the action of the examining board is disapproved by the board of review, the officer shall be considered qualified and shall be promoted.

Section 6. That nothing in this act shall be construed to legislate out of the Service any officer now in the Medical Department of the Army, nor to affect the relative rank on promotion of any medical officer now in the Service, or who may hereafter be appointed therein, as determined by the date of his appointment or commission, except as herein otherwise provided in Section 3.

Section 7. That for the purpose of securing a reserve corps of medical officers available for military service, the President of the United States is authorized to issue commissions as first lieutenants therein to such graduates of reputable schools of medicine, citizens of the United States as shall from time to time, upon examination to be prescribed by the Secretary of War, be found physically, mentally and morally qualified to hold such commissions, the persons so commissioned to constitute and be known as the Medical Reserve Corps. The commissions so given shall confer upon the holders all the authority, rights, and privileges of commissioned officers of the like grade in the Medical Corps of the U. S. Army, except promotions, but only when called into active duty, as hereinafter provided, and during the period of such active duty. Officers of the Medical Reserve Corps shall have rank in said corps according to date of their commissions therein, and when employed on active duty, as hereinafter provided, shall rank next below all other officers of like grade in the U. S. Army: Provided, That contract surgeons now in the military service, who, upon the favorable recommendation of the Surgeon General of the Army shall be eligible for appointment in the Medical Reserve Corps, without further examination, provided that they are not less than twenty-seven

may order officers of the Medical Reserve Corps to active duty in the service of the United States in such numbers as the public interests may require, and may relieve them from such duty when their services are no longer necessary: Provided, That nothing in this act shall be construed as authorizing an officer of the Medical Reserve Corps to be ordered upon active duty as herein provided who is unwilling to accept such service, nor to prohibit an officer of the Medical Reserve Corps not designated for active duty from service with the militia, or with the volunteer troops of the United States, or in the service of the United States in any other capacity, but when so serving with the militia or with volunteer troops, or when employed in the service of the United States in any other capacity, an officer of the Medical Reserve Corps shall not be subject to call for duty under the terms of this section: And provided further, That the President is authorized to honorably discharge from the Medical Reserve Corps any officer thereof whose services are no longer required: And provided further, that officers of the Medical Reserve Corps who apply for appointment in the Medical Corps of the Army may, upon the recommendation of the Surgeon General, be placed on active duty by the Secretary of War and ordered to the Army Medical School for instruction and further examination to determine their fitness for commission in the Medical Corps.

Section 8. That officers of the Medical Reserve Corps when called upon active duty in the service of the United States, as provided in Section 8 of this act, shall be subject to the laws, regulations, and orders for the government of the Regular Army, and during the period of such service shall be entitled to the pay and allowances of first lieutenants of the Medical Corps with increase for length of service now allowed by law, said increase to be computed only for time of active duty: Provided, That no officer of the Medical Reserve Corps shall be entitled to retirement or retirement pay, nor shall he be entitled to pension except for physical disability incurred in the line of duty while in active duty: And provided further, That nothing in this act shall be construed to prevent the appointment in time of war of medical officers of volunteers in such numbers and with such rank and pay as may be provided by law.

Section 10. That all acts and parts of acts in conflict with the provisions of this act are hereby repealed.

## Public Health and Marine Hospital Service:

*Official list of changes in the stations and duties of commissioned and non-commissioned officers of the United States Public Health and Marine Hospital Service for the seven days ending April 8, 1908:*

**BLUE, RUPERT**, Passed Assistant Surgeon. Detailed to attend the meetings of the State Health Officers of California, at Coronado, Cal., April 20, 1908, and of the State Medical Society, at the same place, April 21, 1908, and to attend the meeting of the City Board of Health at San Diego, Cal.

**BRYAN, W. M.**, Assistant Surgeon. Bureau orders of March 25, 1908, assigning to temporary duty at the quarantine station, Quarantine, La., amended to read "for duty and assignment to quarters."

**CARMICHAEL, D. A.**, Surgeon. Leave of absence granted for ten days from March 25, 1908, on account of sickness, amended to read for six days.

**DELGADO, J. M.**, Acting Assistant Surgeon. Granted leave of absence for twenty-three days from March 3, 1908, on account of sickness.

**FAUNTLEROY, CHARLES M.**, Assistant Surgeon. Directed to report to the medical officer in command, New Orleans, La., for duty and assignment to quarters.

**GOLDBERGER, JOSEPH**, Passed Assistant Surgeon. Granted leave of absence for five days from March 3, 1908, under provisions of paragraph 191, Service Regulations.

**HAMILTON, JAMIN H.**, Acting Assistant Surgeon. Granted leave of absence for thirty days from February 22, 1908, on account of sickness.

**HART, LASHER**, Assistant Surgeon. Directed to proceed to Stapleton, N. Y., reporting to the medical officer in command at that port for duty and assignment to quarters.

**HOLT, E. M.**, Pharmacist. Directed to proceed to New Orleans, La., for special temporary duty, upon completion of which to rejoin his station.

**KEEN, W. H.**, Pharmacist. Granted leave of absence for two days from March 30, 1908, under paragraph 210, Service Regulations.

**KRULISH, E.**, Assistant Surgeon. Granted leave of absence for two days from March 24, 1908, under paragraph 191, Service Regulations.

**LANZA, A. J.**, Assistant Surgeon. Relieved from duty at the Marine Hospital at San Francisco, Cal., and directed to report April 15, 1908, to the commanding officer of the revenue cutter *Manning*.

**McCONNON, GEORGE H.**, Assistant Surgeon. Directed to proceed to Port Townsend, Wash., reporting to the commanding officer of the U. S. revenue cutter *Rush* for duty.

**MATTHEWS, H. S.**, Passed Assistant Surgeon. Directed to report to the medical officer in command at the quarantine station, Quarantine, La., from time to time, for the purpose of examining aliens reported to be public charges.

**OAKLEY, J. H.**, Passed Assistant Surgeon. Directed to assume temporary charge of the Marine Hospital at Port Townsend, Wash., during the absence of Surgeon Stimpson on leave.

**OLESEN, ROBERT**, Assistant Surgeon. Directed to proceed to San Francisco, Cal., reporting to the medical officer in command for duty and assignment to quarters.

**ROBERTS, NORMAN**, Assistant Surgeon. Directed to proceed to Baltimore, Md., from time to time, for special temporary duty, upon completion of which to rejoin his station.

**RUCKER, W. C.**, Passed Assistant Surgeon. Detailed to attend the meetings of the State Health Officers of California, at Coronado, Cal., April 20, 1908, and of the State Medical Society, at the same place, April 21, 1908, and to attend the meeting of the City Board of Health at San Diego, Cal.

**RYDER, L. W.**, Pharmacist. Granted leave of absence for three days from April 6, 1908, under paragraph 210, Service Regulations.

**SIMONSON, G. T.**, Acting Assistant Surgeon. Leave of absence granted for two days from March 31, 1908, revoked.

**STEARNS, H. H.**, Acting Assistant Surgeon. Granted leave of absence for one day, March 27, 1908, under paragraph 210, Service Regulations.

**STIMPSON, W. G.**, Surgeon. Bureau order of March 11, 1908, directing to report to the commanding officer of the revenue cutter *Thetis* for temporary duty, revoked; granted leave of absence for six days from April 7, 1908.

**STONER, G. W.**, Surgeon. Granted leave of absence for five days from March 30, 1908, under paragraph 189, Service Regulations.

**THOMAS, J. M.**, Acting Assistant Surgeon. Directed to make inspection of certain stations in Cuba, returning to New Orleans upon completion thereof.

**VAN NISS, GEORGE I.**, Pharmacist. Granted leave of absence for thirty days from April 3, 1908.

**WALKER, R. T.**, Acting Assistant Surgeon. Granted leave of absence for twenty days from April 27, 1908.

**WARNER, H. J.**, Assistant Surgeon. Directed to proceed to Baltimore, Md., reporting to the medical officer in command at that port for duty and assignment to quarters.

**WERTENBAKER, C. P.**, Surgeon. Directed to proceed to Cape Charles quarantine station for special temporary duty, upon completion of which to rejoin his station at Norfolk, Va.

**WETMORE, W. C.**, Acting Assistant Surgeon. Granted leave of absence for one day from March 31, 1908, under paragraph 210, Service Regulations.

**WIGHTMAN, WILLIAM M.**, Assistant Surgeon. Relieved from duty at Callao, Peru, and directed to proceed to Guayaquil, reporting to Passed Assistant Surgeon Lloyd for duty.

**WILSON, J. G.**, Acting Assistant Surgeon. Granted leave of absence for two days from March 21, 1908, under paragraph 210, Service Regulations.

**WOOD, CHARLES A.**, Assistant Surgeon. Directed to proceed to Baltimore, Md., reporting to the medical officer in command at that port for duty and assignment to quarters.

## Appointments.

Dr. H. J. Warner commissioned as Assistant Surgeon in the Public Health and Marine Hospital Service, April 3, 1908.

Dr. Charles T. Wood commissioned as Assistant Surgeon in the Public Health and Marine Hospital Service, April 3, 1908.

Dr. Charles M. Fauntleroy commissioned as Assistant Surgeon in the Public Health and Marine Hospital Service, April 3, 1908.

Dr. Robert Olesen commissioned as Assistant Surgeon in the Public Health and Marine Hospital Service, April 4, 1908.

Dr. George H. McConnon commissioned as Assistant Surgeon in the Public Health and Marine Hospital Service, April 6, 1908.

Dr. Lasher Hart commissioned as Assistant Surgeon in the Public Health and Marine Hospital Service, April 6, 1908.

*Resignations.*

Passed Assistant Surgeon H. A. Stansfield; resignation accepted by direction of the President, to take effect March 23, 1908.

Acting Assistant Surgeon W. J. Linley resigned, to take effect April 1, 1908.

*Boards Convened.*

Boards of medical officers were convened to meet on April 9, 1908, for the purpose of making physical examination of such officers of the U. S. Revenue Cutter Service as should present themselves for that purpose, as follows: New York, N. Y.: Passed Assistant Surgeon H. W. Wickes, chairman; Acting Assistant Surgeon, T. Mahoney, recorder.

San Francisco, Cal.: Surgeon H. W. Austin, chairman; Passed Assistant Surgeon C. H. Gardner, recorder.

Baltimore, Md.: Surgeon L. L. Williams, chairman; Passed Assistant Surgeon J. T. Burkhalter, recorder.

Wilmington, N. C.: Passed Assistant Surgeon C. H. Lavinder, chairman; Acting Assistant Surgeon \_\_\_\_\_, recorder.

Key West, Fla.: Surgeon C. E. Banks, chairman; Acting Assistant Surgeon S. W. Light, recorder.

Mobile, Ala.: Surgeon G. M. Guiteras, chairman; Acting Assistant Surgeon J. O. Rush, recorder.

Port Townsend, Wash.: Passed Assistant Surgeon J. H. Oakley, chairman; Acting Assistant Surgeon Robert Lyall, recorder.

**Army Intelligence:**

*Official list of changes in the stations and duties of officers serving in the medical department of the United States Army for the week ending April 11, 1908:*

CARTER, W. F., Major and Surgeon. Appointed a member of an examining board to meet at Fort Monroe, Va., for the examination of officers of the Coast Artillery Corps for promotion.

DAVIS, W. R., Captain and Assistant Surgeon. Appointed a member of an examining board to meet at Fort Baker, Cal., for the examination of applicants for commission in volunteer forces.

JUENEMANN, G. F., First Lieutenant and Assistant Surgeon. Appointed a member of an examining board to meet at Fort Baker, Cal., for the examination of applicants for commission in volunteer forces.

LAGARDE, L. A., Lieutenant Colonel and Deputy Surgeon General. Arrived at Denver, Col., for duty as Chief Surgeon, Department of Colorado.

RAGAN, C. A., First Lieutenant and Assistant Surgeon. Appointed a member of an examining board to meet at Fort Monroe, Va., for the examination of officers of the Coast Artillery Corps for promotion.

**Navy Intelligence:**

*Official list of changes in the medical corps of the United States Navy for the week ending March 14, 1908:*

ABEKEN, G. F., Passed Assistant Surgeon. Detached from the naval training station, San Francisco, Cal., and ordered to the *West Virginia*.

BACON, S., Acting Assistant Surgeon. Ordered to duty at the Naval Hospital, New Fort Lyon, Col.

BIELLO, J. A., Acting Assistant Surgeon. Ordered to duty at the Naval Hospital, Portsmouth, N. H.

BISHOP, L. W., Passed Assistant Surgeon. Detached from the naval training station, Newport, R. I., and ordered to the *Hancock*.

GREEN, E. H., Medical Inspector. Detached from the Navy Yard, New York, and ordered to command the Naval Hospital, New York, N. Y.

HARMON, G. E. H., Medical Director. Detached from command of the Naval Hospital, New York, N. Y., and ordered home to await orders.

HOUGH, F. P. W., Acting Assistant Surgeon. Ordered to the naval proving ground, Indian Head, Md.

LUNG, G. A., Surgeon. Detached from the *Hancock* and ordered to the Navy Yard, New York, N. Y.

MCGUIRE, L. W., Acting Assistant Surgeon. Ordered to duty at the Naval Hospital, Charleston, S. C.

MELBORN, K. C., Acting Assistant Surgeon. Ordered to the *Wabash*.

MORGAN, C. R., Acting Assistant Surgeon. Resignation accepted, to take effect April 8, 1908.

PAGE, J. E., Surgeon. Retired from active service from April 3, 1908, under the provisions of section 1453, Revised Statutes.

PLUMMER, R. W., Passed Assistant Surgeon. Ordered to the *Idaho*.

RHOADES, G. C., Acting Assistant Surgeon. Ordered to the *Franklin*.

RICHARDS, T. W., Surgeon. Ordered to the *Kansas* when discharged from treatment at the Naval Hospital, Mare Island, Cal.

STALNAKER, P. R., Assistant Surgeon. Detached from the *West Virginia* and ordered to instruction at the Naval Medical School, Washington, D. C.

STEARNE, Assistant Surgeon. Appointed assistant surgeon from March 19, 1908.

WICKES, G. L., Passed Assistant Surgeon. Commissioned a passed assistant surgeon from April 12, 1908.

ZIEGLER, J. Z., Acting Assistant Surgeon. Appointed an acting assistant surgeon from April 6, 1908.

**Births, Marriages, and Deaths.***Married.*

BROPHY—STRAWBRIDGE.—In Moorestown, New Jersey, on Tuesday, March 31st, Dr. Thomas W. Brophy, of Chicago, and Mrs. Esther W. Strawbridge.

DOUGLASS—ELLIS.—In Rome, New York, on Saturday, April 4th, Dr. Adelbert C. Douglass, of Ilion, and Miss Frances H. Ellis.

HAYDEN—HOWARD.—In Washington, D. C., on Thursday, April 2d, Dr. Reynolds Hayden, United States Navy, and Miss Belle Howard.

WETZEL—WHALEY.—In Covington, Ohio, on Friday, April 3d, Dr. Henry S. Wetzel, of Dayton, and Miss Mary Whaley, of Osborne.

*Died.*

BENNETT.—In Battle Creek, Michigan, on Wednesday, April 1st, Dr. C. T. Bennett, aged sixty-three years.

BLACK.—In Louisville, Kentucky, on Sunday, April 5th, Dr. Edward Henry Black, aged eighty-eight years.

CABANNE.—In St. Louis, Missouri, on Tuesday, April 7th, Dr. James Shepard Cabanne, aged sixty-nine years.

CLAGETT.—In Baltimore, Maryland, on Saturday, April 4th, Dr. Joseph E. Clagett, aged seventy-seven years.

CLAPP.—In Geneva, New York, on Saturday, April 28th, Dr. Henry D. Clapp, aged thirty-four years.

EGERT.—In Holland Patent, New York, on Wednesday, April 1st, Dr. Philip Merriman Egert, aged forty-four years.

GRIFFITHS.—In Louisville, Kentucky, on Friday, April 10th, Dr. George W. Griffiths, aged fifty years.

HARWOOD.—In Sandwich, Ontario, Canada, on Monday, April 6th, Dr. Charles Harwood, aged sixty-three years.

HIGBEE.—In St. Paul, Minnesota, on Friday, April 3d, Dr. Chester Goss Higbee, aged seventy-three years.

LOWENGRUND.—In Philadelphia, on Wednesday, April 1st, Dr. Lee Lowengrund, aged fifty-five years.

MARTIN.—In Mendota, Washington County, Virginia, on Friday, April 3d, Dr. J. T. Martin, aged sixty-three years.

MOLYNEAUX.—In Woodland, Illinois, on Friday, April 3d, Dr. James C. Molyneaux, aged fifty years.

O'CONNELL.—In Montclair, New Jersey, on Saturday, April 4th, Dr. Joseph Francis O'Connell, aged fifty years.

PEAKER.—In Toronto, Canada, on Sunday, April 5th, Dr. J. W. Peaker, aged forty-three years.

ROUSE.—In York, Pennsylvania, on Friday, April 10th, Dr. Samuel J. Rouse, aged eighty years.

SELDEN.—In Hampton, Virginia, on Saturday, April 4th, Dr. Charles Selden, aged seventy years.

STEBBINS.—In Geneva, New York, on Wednesday, April 8th, Dr. James H. Stebbins, aged seventy-four years.

THOMSON.—In Belchertown, Massachusetts, on Sunday, March 20th, Dr. Edmond Fanford Thomson, aged forty years.

WESTLAKE.—In Elizabeth, New Jersey, on Tuesday, April 7th, Dr. Warren Carter Westlake, aged fifty-eight years.

### AN ORIGINAL METHOD OF OPERATING FOR CONGENITAL DISLOCATION OF THE HIP.\*

#### *A Preliminary Report of Cases.*

By RUSSELL A. HIBBS, M. D.,

New York,

*Surgeon-in-Chief of the New York Orthopaedic Dispensary and Hospital, etc.*

Without an anæsthetic in the average uncomplicated case of congenital dislocation of the hip in a child up to the fourth year (Fig. 4), and under an anæsthetic in those older, it is possible by flexing and adducting the thigh on the abdomen, and extending the leg on the thigh to force the head down, below, and behind the acetabulum. The route which the head follows in its course downward is behind the acetabulum.

It seemed to me possible, therefore, that if in extending and abducting the thigh in an attempt to bring the leg back to its former position, parallel to its fellow, some means could be devised by which the head could be forced to travel upwards by a more anterior route, a reduction of the dislocation could be secured, as the acetabulum would be directly in the way of the anterior route. Assuming, of course, that the acetabulum was large enough to receive the head, both of approximately normal shape and size. Two things appeared indispensable to the accomplishment of this result: first, absolute control of the pelvis, and, second, an immovable trochanteric pad so shaped and held against the trochanter as to direct the head upward and forward. Such resistance as the capsule or the Y ligament might offer to the reduction would certainly not be increased by such a method and might be diminished, while the muscular resistance, so serious an obstruction to reduction by the Lorenz method, would be entirely avoided, with the injuries not only to the muscles themselves, but often to other important structures, consequent upon the application of a force necessary to overcome that resistance.

Figs. 1 and 2 show an instrument which I have devised and used for this purpose. This consists of a board two inches thick, six feet long, and two feet wide, with two windlass pulleys on the under surface. In the board there are two openings made (Fig. 2), A and B, for the trochanteric pad. At points C and D are attachments for the pelvic straps, and at E is a roller over which the straps run. The child is placed on the board with its sacrum resting on the solid board between the two openings, A and B. The two pelvic straps are at

tached at points C and D, which are widely enough separated for the straps to pass just internal to the crest of the ilium, down over the ramus of the pubis running over the roller just in front of the perinæum, E, on the under surface of the board, to be attached to the two windlass pulleys.

By means of the windlass sufficient pressure may be made on these straps to hold the pelvis in an absolutely immovable position, without the slightest damage to the skin or any other part. The force is exerted laterally against the sides of the pelvis, as well as backward. In locating C and D, the points of attachment for these straps, it is important to have them separated sufficiently to insure this lateral direction of the force, and the distance will vary with the size of the pelvis. The openings, A and B, in the board are sufficiently large to allow the trochanteric pad, which is five inches by one and one-half inches in size, triangular in shape, and hollow, to pass through, upwards. This pad is attached to the under surface of the board by an adjustment which makes it easy to apply it to either side, and by means of a worm screw mechanism it can be forced up by the operator with ease against the trochanter to any point where it remains immovable. The direction of the pad in its immediate relation to the trochanter is determined and fixed by a ball and socket adjustment. This pad is made of highly polished steel, as such a surface slides over the skin with the least possible friction. This instrument may be attached to any plain wooden table, and is simple and inexpensive in construction.

With this instrument, in its more or less incomplete form, I have operated on fourteen hips—in thirteen patients with absolute success in placing the head in the acetabulum in each without traumatism. In regard to the stability of the reduction, since the integrity of all the muscles and structures about the joint is not impaired, may they not furnish such stability to the reduction as will make a redislocation less likely to occur? The greater tension placed upon them by the increase in the length of the limb would seem a distinct advantage. This same fact would shorten the duration of the after treatment and the wearing of a fixed dressing, and enable an early resumption of the normal function of the limb. Such has been the experience in the cases herein reported.

May it not be possible that some of the failures by the Lorenz method, which we have considered as due to the shallowness of the acetabulum, were really due to the destruction of the resistance of those structures which hold the head in its proper relation to the socket, done by the stretching neces-

\*Presented at the Section on Orthopaedics, at the Academy of Medicine, April 1, 1908.

sary by that operation to secure a reduction? In operating with this instrument there is no traumatism of any consequence. These children have all walked, several the next day after the operation,

FIG. 1.—Showing complete instrument used in operation for congenital dislocation of the hip.

and all within three days. The older cases have complained of slight pain at first. The only traumatism that suggests itself as possible, in the use of such force as is here used, is a fracture of the neck of the femur. This has not occurred in any of the cases, and with ordinary judgment I think the possibility remote, because the force exerted upon the femur at all times is in two directions, namely, abduction and extension, and by the operator's hand.

It would seem possible to secure a reduction by forcing the trochanteric pad upwards, but here you have a force which cannot be measured by the operator so accurately.

CASE I.—M. R., age three years. Both hips dislocated. The right dislocation reduced April 30, 1907. Left dislocation reduced June 3, 1907. Right hip in plaster nineteen weeks. Left hip in plaster fourteen weeks. Re-

duction December 10, 1907. Plaster applied with leg in 65° abduction and 50° flexion, changed every three weeks, leg being gradually brought to straight line. On March 20, 1908, the plaster removed, limbs were equal, motion free, head in the acetabulum. Leg brace with a hip band applied as a precaution. April 17, 1908, the reduction seems secure. Limbs equal, head in acetabulum, motion free.

CASE IV.—E. M., age three years, male. Left hip one inch shortening. Operation August 13, 1907. In plaster thirteen weeks. Four months since removal of plaster. On April 17th the limbs were equal, motion free, head in the acetabulum, and result perfect.

CASE V.—M. O'F., age two years six months. Left hip one half inch shortening. Operation September 10, 1907. In plaster thirteen weeks. Four months since removal of plaster. Limbs equal, motion free, head in the acetabulum, and result perfect.

CASE VI.—M. McP., age two years. Both hips dislocated. Operation September 13, 1907, on right hip only. Died on November 1, 1907, of empyema, following pneumonia. Reduction remained secure to time of death.

CASE VII.—S. H., age five years nine months. Left hip one and one half inches shortening. Operation November 14, 1907. In plaster eight weeks. Nearly three months since removal of plaster. Limbs are equal, motion free, head in the acetabulum, and result perfect. April 17, 1908.

CASE VIII.—K. S., age eleven years. Right hip two inches shortening. Operation December 12, 1907. Plaster removed February 19, 1908. In plaster ten weeks. Walks with limb slightly abducted, with slight flexion at the knee. Reduction seems perfectly stable. April 17, 1908: Head in the acetabulum, motion free, limbs equal.

CASE IX.—F. R., age six and one half years. Left hip one and one eighth inches shortening. Operation February 11, 1908. Plaster removed April 4, 1908. In plaster seven weeks. April 17, 1908: Head in the acetabulum, limbs equal, motion free. Reduction seems secure.

CASE X.—M. M., age nine years nine months. Left hip one and one half inches shortening. Operation February 18, 1908. Plaster removed March 28, 1908. In plaster a little over five weeks. February 17, 1908: Limbs equal, head in acetabulum, joint motion free, 10° flexion of knee, and slight abduction of thigh. It may be of interest to add that in this case the Lorenz method was attempted unsuccessfully in another hospital.

CASE XI.—H. F., age eleven years. Left hip one and one

FIG. 2.—Upper surface of instrument, showing pelvic straps, openings for trochanteric pad, etc.

sult on April 17, 1908: Head of femur in the acetabulum in each hip, limbs parallel and equal, motion free, result perfect.

CASE II.—A. M., twenty-one months old. Left hip dislocated, three quarter inch shortening. Operation July 5, 1907. In plaster fourteen weeks. Head in the acetabulum, limbs equal, motion free, and result perfect, April 17, 1908.

CASE III.—M. W., age two years. Left hip dislocated, one half inch shortening. Operation July 5, 1907. In plaster thirteen weeks. Taken from hospital by mother aged two years and four months, immediately after the removal of the plaster. Was again admitted with redislocation. Sec-

ond operation December 10, 1907. Plaster applied with leg in 65° abduction and 50° flexion, changed every three weeks, leg being gradually brought to straight line. On March 20, 1908, the plaster removed, limbs were equal, motion free, head in the acetabulum. Leg brace with a hip band applied as a precaution. April 17, 1908, the reduction seems secure. Limbs equal, head in acetabulum, motion free.

CASE XII.—Jennie D., age four years and six months. Right hip one and one quarter inches shortening. Operation March 6, 1908, before the Interurban Orthopedic Club. Plaster removed April 13, 1908. Head in acetabulum, limbs equal, reduction seems secure. April 17th

FIG. 3, A.—First step of operation.

CASE XIII.—Jennie R., age eleven years. Left hip one and seven eighths inches shortening. Operation March 17th. Limb put in plaster parallel with its fellow, including knee. April 2, 1908: Knee freed. Plaster removed April

FIG. 3, B.—Second step of operation.

13th. Head in acetabulum, limbs equal, reduction secure April 17th.

In each instance the reduction has been confirmed by an x ray taken immediately after the

FIG. 3, C.—Third step of operation.

operation with the limb in plaster, and in every case after its removal.

Thus we have fourteen hips in thirteen children which we may consider as having the head in the acetabulum, and in most cases a sufficient time has elapsed to make it safe to say that the reduction is stable. In one, Case III, the dislocation recurred;

FIG. 4, A.—X ray of Case XII. Shows dislocation.

the limb now seems stable. In Case VI the patient died while in plaster. In Case XI the shallow acetabulum makes it doubtful that reduction will be secure. However, it is so now.

The steps of this operation are shown in the illus-

FIG. 4, B.—X ray of Case XII. Shows the position in which the limb was placed, without any plaster, just before operation.

trations (Fig 3, A, B, C) and are: First, the child is placed upon the table, and the pelvic straps attached, then the leg to be operated on is flexed on the abdomen. At this point, by the windlass, the pelvis is made immovable by tightening the straps.

Second, the leg is extended on the thigh, with the thigh held in adduction and flexion on the ab-

domen, thus forcing the head below the acetabulum. At this point the operator, by means of the wheel and worm screw mechanism, forces the trochanteric pad, it being so set by the ball and socket adjustment as to direct the head upward and forward, firmly against the trochanter, and then the thigh is extended and abducted, forcing the head to travel upward, anteriorly, into the acetabulum. The degree of extension of the thigh necessary before the head reaches the acetabulum in its course upward will depend upon the distance below the acetabulum at which it rests when the thigh is in flexion and adduction on the abdomen and the leg extended, and will be less in the older cases. The lower the

will vary with the age of the patient, being greater in those with most shortening. However, in some cases, as in Case XIII, age eleven, the leg was brought to a position of  $10^{\circ}$  abduction and  $180^{\circ}$

FIG. 5.—Case XIII, first plaster

head is gotten the easier will be the reduction, as when it is well below the acetabulum it is forced into the anterior route more gradually. The angle of departure from the posterior route, traveled in its descent, is more acute. The sensation when the reduction is accomplished can hardly be mistaken, and the snap can often be heard. The muscles become taut, and the leg flexed.

Third, plaster is then applied with the thigh in abduction and flexion, so as to put considerable tension on the muscles, and the knee is included in the plaster with the leg extended so the ham strings are tense. The angles of abduction and flexion

FIG. 6.—First plaster, Case VIII, showing degree of flexion.

extension in the first plaster. The first plaster should be changed at the end of two weeks, when it will be found possible to place the limb nearer the normal position, and the plaster should be changed every two weeks until its removal. I

FIG. 7.—Case VIII First plaster, showing degree of abduction

doubt the necessity of any case wearing plaster more than two months, and at the most three, and in many a shorter time.

The ages of the cases herein reported, varying as they do from twenty-one months to eleven years, suggests that cure may be effected more quickly in all cases, than by the Lorenz method, for instance, and that the upper age limit where perfect results may be obtained may be increased.

Is it not possible also that the number of cases in which an anterior transposition has been considered a good result may be smaller?

All these cases were treated in the New York Orthopaedic Hospital and this instrument was made in its shop.

130 EAST THIRTY-SIXTH STREET.

## SUDDEN BLINDNESS AND ITS VARIOUS CAUSES.\*

By MARY BUCHANAN, M. D.,  
Philadelphia.

**Sudden blindness:** The words strike terror to the hearts of the strongest of us! Modern man's enjoyment comes so largely through his sight that the mere thought of such a fate being ours causes each to cry instinctively, "Rather let me die!" Sudden loss of vision, however, like sudden death, spares its victim the horror of anticipation.

Sudden blindness in both eyes simultaneously is, fortunately, rare; in one eye it is not infrequent, and partial loss of vision is quite common. Blindness, more or less complete, whether monocular or binocular, is often spoken of as "amaurosis," while that of lesser degree, and generally without apparent fundus or other lesion, is called "amblyopia." We will consider briefly first, sudden binocular blindness; then monocular; and third, partial blindness, sudden in its onset.

Sudden complete blindness in both eyes, barring traumatism (gunshot injuries, lightning stroke, etc.) suggests always a systemic origin. Among the more important of these causes may be mentioned those usually classed as toxæmias, notably uræmia; malaria; anæmia, due, for instance, to a profuse general hæmorrhage; drugs and poisons, such as quinine, lead, and methyl alcohol.

In regard to gunshot wounds of the head causing blindness, it is interesting to note that the would be suicide who puts the revolver to the temple and fires rarely succeeds in his purpose; the bullet plows through the orbit and severs the optic nerve, or at times goes through the chiasm, and instead of sudden death sudden blindness is his portion.

Uræmic amaurosis is most frequent in the nephritis of scarlatina and pregnancy. It is more common in acute than in chronic nephritis. It is generally preceded by headache, but develops suddenly, is bilateral and passes rapidly into complete blindness, which may remain permanent or may be relieved, depending upon the course of the nephritis.

The fundus picture is negative and the pupils react to light, showing the cortical nature of the affection, as the reflex arc of the pupil is not connected with the cortex directly. The secretion of urine is diminished or suspended, the specific gravity is

high, and the urine contains a large amount of albumin. The usual symptoms of uræmia are present, and the treatment is for this condition.

The restoration of sight is at times sudden and occurs in from twenty-four to thirty-six hours, or, as Knies states, "when the nephritis is capable of recovery the blindness may also disappear, otherwise it indicates the beginning of the end."

The blindness produced by methyl alcohol poisoning is bilateral and generally complete. It may set in a few hours after ingestion of the poison (for it is a poison), or it may be delayed several days. There is subsequent improvement in vision, but finally a relapse into permanent blindness.

Methyl alcohol, or wood alcohol poisoning, is becoming much more frequent of late because the relative cheapness of the drug (50 cents per gallon against \$2.60 per gallon for ethyl alcohol) leads to its use in cheap whiskeys, Jamaica ginger, lemon extracts, bay rum, cologne water, Florida water, Columbian spirits, Cologne spirits, standard spirits, union spirits, eagle spirits, etc., and also because of increase of local option and prohibition states, which makes it impossible for men to purchase alcoholic beverages for drinking purposes, so they resort to subterfuge; they buy it for external use, or drink one of the above preparations. Dr. Frank Buller and Dr. Casey Wood made an exhaustive study and reported of these cases in 1904 for the Ophthalmic Section of the American Medical Association, and found that 153 cases of blindness and 122 deaths had been traced to this poison; they stated that the total would reach 400 if a more thorough search were made. I quote the following from their conclusions:

The symptoms are gastrointestinal disturbances, more or less severe, with pain, general weakness, nausea, vomiting, vertigo, headache, dilated pupils, and blindness. If recovery does not occur there is marked depression of the heart's action, sighing respiration, cold sweats, delirium, unconsciousness, coma, and death.

Acute abdominal distress followed by blindness should always suggest methyl alcohol poisoning. The visual fields, if blindness is not complete, are contracted and show a central absolute scotoma, that is, there is no perception of color or light in the area.

Individuals differ as to their susceptibility to the poison, and toxic symptoms may even be produced by inhalation or by methyl alcohol fumes. Treatment consists in the use of the stomach pump and stimulants, especially ethyl alcohol, strychnine, and coffee, and external heat. The treatment of the blindness is unsatisfactory; pilocarpine and potassium iodide may be given early, later strychnine.

Malarial poison acting upon the optic nerves and retina may cause a loss of vision or complete blindness, lasting from several hours to days or months. It disappears under malarial treatment.

Quinine in large doses may produce total blindness due to spasm of the vessels diminishing the blood supply and causing, according to Ward Holden, a degeneration of the ganglion cells and nerve fibres of the retina and optic nerve. The pupils are dilated and do not respond to light, and there is also associated with this tamus and deafness. Central vision may be restored, but the peripheral field will remain cut. The treatment is with withdrawal of the drug, and the administration of amyl nitrite and strychnine.

Lead poisoning has been known to cause sudden binocular blindness, probably central in origin.

Excessive hæmorrhages, particularly from the

\*Read before the West Philadelphia Branch of the Philadelphia County Medical Society, February 14, 1908.

stomach, may cause sudden loss of sight, which may be only temporary or may end in optic atrophy and permanent loss of vision. The ophthalmoscope shows a pale disk and contracted arteries. The lesions in the unfavorable cases do not appear until a week or more after the hæmorrhage. Uterine cases give the most favorable prognosis.

Transitory blindness sometimes occurs with brain tumors, particularly, according to Bruin, with those of the occipital lobes. Hirschberg denies that blindness in these cases is a localizing symptom.

Malingers sometimes feign sudden blindness of both eyes for gain, or to escape military duty. These people must be closely watched. Priestly Smith and E. Jackson give the following test for feigned blindness:

Place a lighted candle in front of the subject; now hold a 6 degree prism base out before one eye; if both eyes see, the one behind the prism will move inward, and on removing the prism will move outward, the other eye remaining fixed. The explanation of this is that the prism throws the

embolism of the central artery, complete detachment of the retina, or an extensive hæmorrhage into the vitreous chamber.

In embolism of the central artery the history is a sudden blindness, coming on without warning, without exertion, often on awaking from a sound sleep. We expect to find this in a patient with a heart lesion, but this cannot always be demonstrated clinically. The diagnosis can readily be confirmed with the ophthalmoscope, for the picture is unique. (See Fig. 1.) There is a cherry red spot in the macula which stands out well against the white background, the disk edges are not visible on account of the swelling, and the arteries are reduced to threads. It is a tragic picture, for our only chance is in dislodging the obstruction and that immediately, for the ganglion cells, which depend for their nourishment upon the retinal vessels, are soon starved to death and rapidly degenerate. Very few cases of embolism, if any, recover vision.

Complete detachment of the retina is not apt to occur spontaneously in a previously healthy eye. There is a history of a fall, a blow, or a nearsighted or diseased eye. An eye that has a detached retina is always soft on pressure. If you will recall the anatomy of the eye for a moment you will remember that the retina has firm attachment only at the optic nerve entrance, and anteriorly in the ciliary region; hence it must be held in place by the vitreous body. It can become detached by being pushed away by an exudate or a tumor beneath, or through the lack of support from a diseased or fluid vitreous body. A nearsighted eye often has a fluid vitreous body, and with its weakened and stretched coats is in danger of detached retina.

In these cases you get a gray reflex by throwing a strong light into the pupil, but it is deep, because the clear lens is in front of it. Possibly there has been a slight detachment before, to which the patient has paid no attention, but questioning will bring out the fact that he had noticed a moving cloud or curtain before his eyes. This is what the patients with partial detachment complain of. Detachment generally begins above, and then the fluid sinks gradually to the lower portion of the eye and increases until there is a total separation and blindness.

The prognosis of total detachment is absolutely hopeless, and while we rarely have both eyes lost through embolism, it is not unusual to have detachment in both eyes, although not simultaneously, because the same predisposing causes are apt to be present. These patients must be cautioned as to their danger, for even with the best of care as to correct glasses, avoidance of close work, violent exercise, etc., detachment may occur.

Sudden profuse hæmorrhage into the vitreous chamber will cause complete loss of vision, and to the ophthalmoscope presents a dark, impenetrable mass. It is not apt to occur unless there has been traumatism, or there is disease of the bloodvessels, or a blood dyscrasia.

Thrombosis of the central retinal vein causes almost complete loss of sight at the time of occurrence and may ultimately lead to permanent blindness. The ophthalmoscopic picture is typical; the veins are engorged, the arteries are reduced to

FIG. 1. Embolism of the central artery.

candle image inward, causing two candles to appear, but the impulse for binocular vision makes the eye move involuntarily so as to fuse the images into one.

It is not safe to depend upon the reaction of the pupils to light, because if the lesion is behind the corpora quadrigemina, the pupils will still react, although the patient is blind.

Mind, psychic, or object blindness, may appear suddenly. It is that condition in which the individual, because of cerebral lesion or disturbances, is unable to recognize familiar objects.

Burr reports a case in a woman sixty years of age who, while sitting at the table, suddenly lost vision. When he examined her she could not tell a watch when placed in her hands, and she could not feed herself because she could not recognize knife, fork, or spoon.

Before these cases are classified as mind blindness they should be carefully studied to exclude all peripheral causes.

Hysterical blindness is rarely bilateral.

Complete sudden loss of sight in one eye without external signs of inflammation suggests immediately

threads, the outline of the disk is obliterated, and the fundus is covered with numerous hæmorrhages. (See Fig. 2.) This is most apt to occur in elderly persons with atheromatous vessels, but may appear as a complication of facial erysipelas. The infection is then carried into the orbit, and the septic thrombus extends from the orbital vein into the retinal vessel. According to Knapp, "if, after the subsidence of an erysipelas involving the orbit, the eye is found to be blind, with optic atrophy and attenuated vessels, we may conclude that there has been a thrombosis of the central retinal vein."

Thrombosis of the retinal veins may be preceded by transitory attacks of blindness, as a premonitory symptom.

These four conditions give no pain, and the external appearance of the eye is normal, but acute glaucoma, on the other hand, which must never be forgotten, produces intense pain and does alter the appearance. Here the eyeball is hard to the touch,

FIG. 2.—THROMBOSIS OF THE CENTRAL VEIN.

the pupil dilated and immovable, the cornea very hazy, like steamed glass, the iris is pushed against the cornea, and there is pain through the ball and over the brow.

The attack causes marked prostration, nausea, and vomiting. These patients are generally middle aged or past it, and their future eyesight and usefulness will depend upon the recognition of the condition by the family physician and his promptness in sending for skilled aid. This is one condition where the ophthalmologist is a necessity.

Sudden unilateral blindness may follow a blow over the orbit, in which case the optic nerve is generally severed or compressed by a splinter of bone. Here the history of traumatism is an aid, and every case of "black eye" should be examined carefully, with the possibility of fracture in mind. An X-ray should be taken at once if vision is reduced or lost. Delay is fatal to the return of sight.

Hæmorrhage into the sheath of the optic nerve or into the orbit may cause blindness, but this may disappear as the blood is absorbed.

A transitory form of monocular blindness has

been recorded in which the blindness lasted about half an hour, and is supposed to be due to a spasm of the vessels. These cases are rare.

Blindness of one eye is often feigned by malingerers or observed in hysterical patients. In a paper read by Dr. H. F. Hansell, before the Ophthalmic Section, College of Physicians, on this subject, mention is made of the difficulty of distinguishing between these two types, particularly where suit for damages is made. Dr. de Schweinitz gave a simple rule to follow, "The blind hysteric is consistent, the patient who pretends to be blind but is not hysterical is not consistent."

There are a number of tests for simulated blindness. One of the commonest is to place a red glass in a trial frame before the good eye and ask the patient to read the red letters on a test card; these cannot be seen through the red glass. Another is to place a strong glass before the good eye through which the patient could not possibly see, and a plane glass before the "blind" eye, and ask the patient to read a distant chart.

Another consideration in these legal cases following injury is that the eye may really be blind, but the condition existed prior to the accident. These patients may declare they saw well before the trauma, and yet an ophthalmoscopic examination reveals a well marked optic atrophy, or a large patch of sclera shining through where smooth choroid and retina should appear. These degenerative changes take at least three weeks and often months before they show up, and would make good vision impossible at the time stated by the plaintiff.

Sudden partial loss of vision may arise from conditions similar to those causing complete loss. Thus an embolism of a branch of the central artery would cause a blind area in the part supplied by that vessel; or partial detachment, a cutting down of the field in the portion corresponding to the part involved. If it is above the patient cannot see the ground, or he notices a cloud waving in front of it. Here again we have a soft eyeball, and generally a prominent, nearsighted eye to aid in the diagnosis. It requires considerable skill to recognize an early detachment with the ophthalmoscope, and even older ones when they are peripheral, and it is in the early stage only that there is hope of replacement and restoration of function.

Retinal hæmorrhage causes more or less blindness, according to its position. A large hæmorrhagic area at the periphery may almost escape unnoticed by the patient, while a tiny one right at the macula may reduce vision to about 1/60 of normal and make reading an impossibility. A blow on the eyeball, diabetes, arteriosclerosis, or anemia are all liable to cause hæmorrhagic retinitis.

An acute inflammation of the orbital portion of the optic nerve will blot out central vision suddenly. This may be caused by prolonged exposure to intense cold, by pressure from the sphenoidal sinus, or inflammation extending from it. A sudden reduction of vision coming on after a cold, or after influenza, should always suggest sinusitis as a possible cause.

Methyl alcohol poisoning of a milder grade than described before will cause sudden central blindness. Prolonged gazing at the sun, as during an eclipse, will produce a temporary central blind spot which

may persist for several days. Improvement in vision may take place, but complete recovery is not common.

The so called "snow blindness" is produced by exposure of the eyes for a long time to the glare of the sun on a large area of snow. This is mostly an affection of the lids and conjunctiva. The lids are red and swollen, there is lachrimation and photophobia with blepharospasm. The condition generally passes off in three or four days without leaving any bad results.

Electric ophthalmia is a condition similar to snow blindness, occurring in those engaged in electric welding, and occasionally in those who use a strong arc light. It comes on within twenty-four hours after exposure, and recovery occurs in a few days with no bad results. Exposure to strong electric light may cause the same effect on the retina as blinding by the sun, that is, there is a central blind spot produced. These workers should wear colored glasses, either yellow, ruby, or a combination of blue and red.

Transitory hemianopsia or scintillating scotoma is, as its name implies, a transient loss of sight in symmetrical portions of the fields of vision which may last from a few minutes to half an hour. The blindness commences over a small area near the macula, with zig zag flashes at its periphery, and gradually spreads over the whole side of the field. It is usually followed by migraine, and is generally classed as a symptom of the latter, though either the scintillation or the migraine may be absent. These attacks usually occur in intellectual individuals; and fatigue, long reading, hunger, and anæmia may produce them. They are probably due to some cerebral circulatory disturbance.

Permanent blindness involving half of each field may occur suddenly. This is known as hemianopsia, and is due to a lesion at the chiasm, at the centre of vision in the cortex, or between these two places. The term is not used when the disease is in the eye itself. If you will recall the anatomy of the brain, you will remember how the optic nerves leave the orbit and join at the optic chiasm, and then pass on as the optic tracts. The fibres from the outer half of each retina do not cross at the chiasm, but continue to the cortex in the tract on their own side, while the nasal fibres cross at the chiasm and join the tract on the other side of the brain. Hence, a lesion of one tract or one cortical centre would destroy vision in the temporal half of one eye and the nasal half of the other eye. If the lesion is in the optic tract, optic radiations, internal capsule, or pulvinar, hemiplegia, motor aphasia, or paralysis of central nerves, may be noted as direct symptoms.

Homonymous hemianopsia is the most common form; that is where the right half or the left half of each field is wanting. In this variety the patient with the left portion of each field cut off is much more fortunate than the one with the right portion gone, because in reading and writing English it is necessary to see ahead to the right, hence a patient with right hemianopsia can neither read nor write. The fact that a certain ward patient's plate always returned with the food remaining on one side of it led to the discovery that he had homonymous hemianopsia. He only ate what he saw.

Bitemporal hemianopsia is where the outer side

of each field is lost. This can only be caused by a lesion at the chiasm, as it is only here that the nasal fibres from each retina meet. Binasal and altitudinal hemianopsia are so rare, and so unlikely to occur suddenly, that they need not be discussed here.

The chief diagnostic symptom of cortical hemianopsia is what is known as *vision nulle*, that is, although the patient knows he has a blind area in each field, he is unconscious of it. It does not bother him any more than the blind spot does a healthy person.

There are also a number of cases in which the clinical history is of sudden blindness in one eye, and close questioning will elicit the fact that the patient suddenly covered the good eye, and *accidentally* discovered that he could not see. Ophthalmoscopic examination will prove that the lesion is a chronic one, and has been so gradual that the other eye has done all the work and the defect has not been noticed. Cataracts are often discovered this way, and grave fundus lesions, because they are painless, often work irreparable destruction on this account.

A large area of chorioiditis may also destroy the retina and choroid without the knowledge of the patient, and be suddenly discovered through some temporary shutting off of vision of the fellow eye. It is strange but true that a case of "pink eye," ordinary catarrhal conjunctivitis, will give a patient much more alarm and cause him to seek medical aid much quicker than the sudden discovery of impaired vision without external inflammation. It is not unusual to get a history of poor sight discovered in a supposedly healthy eye some ten days to six weeks previously. The victims delay, thinking "it will come all right again," and when it does not, they seek the ophthalmologist too late to be of any use, but to be assured that nothing can repair the loss. The retinal tissue is so highly specialized that it rapidly degenerates under pressure, or inflammation. This is a point for the general practitioner to remember, for it is the family doctor that is often first consulted in these cases of sudden blindness. Not infrequently we see eyes stone blind from acute inflammatory glaucoma where the doctor had passed it off with "You've taken cold; bathe it in hot water and it will come around all right." If you do not know what the condition is, don't waste time, but call in the ophthalmologist, just as you would the surgeon in serious abdominal conditions.

324 SOUTH NINETEENTH STREET.

## RADIOGRAPHIC DIAGNOSIS OF RENAL LESIONS.

By LEWIS GREGORY COLE, M. D.,  
New York,

Consulting Radiologist to the Board of Health, Radiologist to  
St. Mary's Hospital for Children

Since the more general practice of nephrotomy has demonstrated the difficulty of diagnosing cases of renal calculi with any degree of certainty, the demand for a more positive method has been apparent, and the discovery of Röntgen, twelve years ago, was at once eagerly seized upon as furnishing this method.

Radiographs of favorable subjects were made showing these lesions, and reports of these cases were heralded around the world, creating in the

minds of the oversanguine the erroneous impression that the x ray furnished a simple and infallible solution of the problem. With the generally limited knowledge of the science then possessed, physicians, surgeons, and instrument makers at once provided themselves with x ray equipments and undertook to make radiographs of renal calculi with what would now be regarded as crude apparatus.

As a result radiographs were made, giving shadows which were interpreted as calculi, but which, in many cases, were not sufficiently distinct to justify a positive diagnosis, and in none of these early plates was there sufficient detail to warrant a negative diagnosis. Such diagnoses were, however, frequently made, and in many cases proved erroneous, with the result that this method fell into disrepute, and it is with considerable difficulty that it is becoming reinstated in its proper place.

Three years ago this spring, after making a number of satisfactory radiographs of the renal and ureteral region, I read a paper before the genitourinary section of the New York Academy on The Negative and Positive Diagnosis of Renal and Ureteral Calculi by the Ray of Selective Absorption, and demonstrated some plates which showed calculi distinctly where the diagnosis had been verified by operation, and others which showed the psoas muscle and the tips of the spinous process distinctly enough to justify a negative diagnosis.

In some of these cases the symptoms of renal calculi were so characteristic that the operation was performed, and in only one patient was a stone found that was not shown in the radiograph, and in that case the plate did not extend high enough up to include the area of the pelvis of the kidney, where the stone was found on operation.

This success continued until the two tubes I was using gave out, and with new tubes the results were not nearly so satisfactory, and for several months it was with great difficulty that I obtained radiographs showing sufficient detail to justify a negative diagnosis.

During the winters of 1904 and 1905 I devoted much time to experimental work on the ray of selective absorption, and the results of this line of work are fully described in the *Archives of the Roentgen Ray*, May, 1905, and further experiments along the same line in the *Archives of Physiological Therapy*, December, 1906, or in the transactions of the *American Roentgen Ray Society*. In brief, this resulted in the separation of the x ray into three distinct varieties: 1, The direct ray; 2, the indirect ray; and 3, the secondary, or Sagnac, ray.

The purely direct ray when it can be obtained gives, on a well timed and properly developed plate, the greatest amount of detail, not only the structure of the bones, but the muscles, fascia, fat, and even the blood in the veins show very distinctly.

The indirect rays from the average tube are equally as powerful and abundant as the direct rays, and their effect is equal to that of the plate, and obscure the detail of the direct rays. It has been demonstrated by Professor J. J. Thomson that the secondary, or Sagnac, rays are generated in some minute form all substances under the action of the x ray in inverse proportion to the density of the

substance, and I am convinced by my own experiments that they are produced to a greater extent by the indirect than the direct rays, and the effect upon the plate is detrimental in the same manner as the indirect rays.

**Compression Blend.**—The use of a diaphragm or compression blend cuts off the indirect rays to some extent and helps very materially in obtaining good radiographs of the renal and ureteral region, but it does not convert any greater percentage of the energy into direct rays.

With an apparatus so constructed that one has a preponderance of direct rays and using a compression blend to eliminate the indirect rays and limit the field in which the secondary rays are generated, we can obtain enough detail to enable one to make a negative or positive diagnosis of renal or ureteral calculi of sufficient size to justify an operation.

**Technique.**—The patient should be prepared for the radiograph by thorough catharsis the night previous and an enema just before the exposure is made. This is especially important when the patient is constipated and the stools are hard and dry. The bladder should also be empty.

**Diet.**—It is desirable that only a light breakfast should be eaten, and that the stomach should be empty before the radiograph is made.

**Clothing.**—The clothing should be removed from the part of the body to be radiographed, not that the clothing interferes so much with the rays, but they are likely to contain buttons, hooks and eyes, or pins, that might lead to a misinterpretation of the negative.

**Position.**—The patient then lies with his back flat on the table and the thighs flexed so that the small of the back is in contact with the plate. Raising the head or shoulders sometimes assists in securing this position.

**Large Plate for Genitourinary Tract.**—If one large plate is to be used to include both kidneys, both ureters, and bladder, the tube is placed vertically over the umbilicus, twenty or twenty-two inches from the plate.

**Size of Plate.**—An 11 x 14 inch plate is the smallest size that will include both kidneys, ureters, and bladder, and if the patient is tall this is not large enough. Just previous to adjusting the plate under the patient it is well to test the tube. As the kidney moves from one half to two inches during respiration, the patient should hold his breath during the exposure, otherwise the shadow of a calculus will appear ill defined and indistinct, and if very small will appear as a blurred line.

**Exposure.**—The time of exposure varies from ten to thirty seconds, according to the size of the patient and condition of the tube. The radiograph should include the eleventh and twelfth vertebrae and ribs above, and extend about six inches beyond the tip of the coccyx below.

**Compression Blend.**—Much more detail may be obtained when a compression blend or diaphragm is used. The compression blend not only compresses the part and holds the patient quiet, but it also prevents the rays from being scattered too far. At the same time it so limits the area exposed that its use requires few radiographs to show the entire tract.

urinary tract, one for each kidney and the upper part of the ureter, one for each ureter, and one for the bladder and lower part of each ureter.

**Renal.**—The radiograph of the kidney region should show the eleventh and twelfth ribs, and the first, second and third vertebræ (lumbar).

**Ureteral.**—The ureteral radiographs extend from the third lumbar vertebra to the brim of the pelvis.

**Bladder.**—The radiograph of the pelvis includes the pubis below and extends up as far as possible.

**Full Set of Plates.**—The necessity of making a full set of plates cannot be too strongly urged. An oculist would not limit his examination to one eye, or an aurist to one ear, nor would a diagnostician make a physical examination of one side of the chest, even although all the pain was on that side. Why should a radiographer make a radiograph of one kidney? In a number of cases, which I will mention later, calculi have been shown on the opposite side from which the pain occurred, or calculi have been present on both sides and only given symptoms on one. If an opinion is desired as to the size, shape, position, and density of the kidney, then surely a radiograph of both kidneys is necessary for comparison.

**Interpretation of Plates.**—The interpretation of the plate is more important and more difficult than making it, and lack of care and experience in this is the cause of most of the errors that have been made in the diagnosis of renal and ureteral calculi by the x ray.

A person unfamiliar with woodcraft is astonished at the way an old hunter can follow the track of an animal in the woods, yet when his attention is called to the barking of a fallen log, the slight imprint in the ground, the turned leaf, or broken twigs, etc., they are all apparent. It is much the same in reading x ray plates—the shadows are there, and any one can see them when they are pointed out.

It requires a careful study and comparison with other plates by a trained eye to detect slight shadows, and it requires experience to determine whether they are due to calculi or one of many other things which I will mention later. This has been especially impressed upon me during the preparation of this paper, when I have studied nearly fifteen hundred plates, made during my practice, some of the earlier ones showing shadows of what I then failed to recognize as possible calculi, requiring repeated exposures for verification.

It is unwise to make a diagnosis on a wet plate: drops of water and the glistening of the wet surface interfere with the detail. The plate should be allowed to dry slowly and the back of the plate thoroughly cleansed and polished. It should then be carefully studied and compared with other plates in a good even light. Some prefer an illuminating box where the light can be controlled with a rheostat, but personally I prefer a northern sky or daylight with a ground glass, holding the plate in my hands so that it may be tilted at different angles to show finer gradations of the shadow.

One is not justified in making a negative diagnosis of renal or ureteral calculus, unless a plate of the renal region shows the following detail, which is shown in Fig. 4. 1. The spine and transverse processes should show distinctly all the way to the tip.

2. The outer border of the psoas muscle must show. In some very flabby, fat patients it may not show as distinctly as the kidneys. 3. The eleventh and twelfth ribs should show distinctly, and in many cases the bony detail may be distinctly seen. 4. In about 75 per cent. of the cases the kidney may be seen more or less distinctly, and if special care in technique is used, it may be shown in nearly every case. 5. The liver is frequently seen, and at times it interferes with showing the convex surface of the upper pole of the right kidney. 6. The spleen also may be seen, especially if it is enlarged or congested. 7. Accumulation of gases in the colon and small intestines appear on circumscribed areas, and folds in the walls of the intestines are often seen traversing these areas. 8. Fæces in the intestines, especially in the colon, show very distinctly, and interfere very materially with the diagnosis of renal lesions.

**Ureteral.**—The plate of the ureteral region should include the third, fourth, and fifth lumbar vertebræ, and part of the sacrum and ilium. The bony detail should show distinctly, and the sacroiliac synchondrosis should be well defined. The outer border of the psoas muscle is clear, and the accumulation of gas and fæces are frequently seen in the cæcum or sigmoid. The course of the ureter is about on a line with the tips of the transverse processes, and at the sacroiliac synchondrosis. Calcified arteries are sometimes seen in the plates.

**Pelvis.**—This plate shows the pubes, bony structure of the spine of the ischium, sacrum, and coccyx all the way to the tip. The bladder distended with urine is sometimes well marked, also when injected.

**Diagnosis.**—Up to the present time the radiographic diagnosis of the genitourinary tract has largely been limited to the negative or positive diagnosis of renal, ureteral, or vascular calculi. We will therefore consider this subject first.

After having made and carefully studied about fifteen hundred plates of the genitourinary tract in about five hundred cases, I believe that a plate having the described detail will show any variety of renal, ureteral, or vascular calculi of sufficient size to justify an operation—that is, one that is too large to pass.

In view of the fact that some of the best authorities disagree with me in this statement, it is with reluctance that I make it, but after carefully experimenting with the softest calculi that I could obtain, and in one case using the very stone it was stated would not show, I am convinced that I am justified in making this statement. I placed the stone behind a patient and made an exposure, and it showed very distinctly on a plate placed behind him. This, of course, is much easier than if it were in the kidney. I then placed it on the abdomen of a large man, and it showed distinctly. This was much more difficult than showing it in the kidney, because the further the calculus is from the plate the less distinct it is. Not satisfied with this, I imbedded this calculus in paraffin and placed it behind a patient the same distance from the plate that it would be if it were in the kidney, and it showed distinctly. Fig. 23 shows a cystine calculus, which is one of the varieties that some authorities claim cannot be shown by x ray.

**Differential Diagnosis.**—In some cases, Figs. 2, 3, 4, 5, 14, 15, 19, 20, 21, 23, and 24, the calculi are so distinct that there is no difficulty in making the diagnosis. In others, Figs. 6 and 7, on account of the size or indistinctness of the shadows, it requires the careful study of several confirmatory plates to make a positive diagnosis or to distinguish between calculi and the following: 1, faecal concretions; 2, gallstones; 3, calcified costal cartilages of the eighth and ninth ribs; 4, spiculae of the bone; 5, small calcarious bodies or so called phleboliths; 6, folds of intestines; 7, enteroliths; 8, foreign bodies in intestines; 9, calcified arteries; 10, calcified lymph-noids; 11, prostatic calculi; 12, finger marks; 13, developing stains from uneven flood of developer; 14, flaws in plates; 15, tuberculous kidney; 16, shot in back; 17, unknown.

1. **Faecal concretions.**—We are most frequently called upon to distinguish between the shadows of calculi and those of faecal concretions, such as shown in Fig. 8, and it is unwise to make this distinction on one plate.

#### Calculus.

If the patient has held his breath, the edges of the calculus will appear clear cut and well defined. The shadows are more dense for their size, and are only seen in the region of the kidney or ureter, and the most important thing is to give time for faecal concretions to move out of the field or change position, and if the shadow remains in the same place it is not faecal concretion.

#### Faecal Concretions.

The edges of the shadows are ill defined, and the shadows less dense than those of calculi of the same size. They are usually multiple and at least some are not in the region of the kidney or ureter, and if time is allowed to elapse between exposures and a cathartic and enema are given, the concretion changes its place or disappears entirely.

2. **Gallstones.**—Gallstones may be shown with patients on back, but are more clearly defined when patient lies with abdomen flat on the plate. The reverse is true of renal calculi. Shifting the tube slightly changes the position of the shadow of the gallstone more than it does the shadow of the kidney stone.

3. **Calcified costal cartilages of the eighth and ninth ribs.**—The calcified costal cartilages of the eighth and ninth ribs resemble renal calculi very closely. They may appear, as is shown in Fig. 9, in the kidney in the same positions in repeated exposures. There is usually more than one costal cartilage calcified, which gives the appearance of a calcarious deposit throughout the kidney, more than an isolated calculus, or two or three calculi, and are usually bilateral. They may be definitely distinguished from calculi by having the lip of the compression blend under the free border of the ribs; therefore, when ever the shape of a person is such that the compression blend must be on top of the free border of the ribs in order to include the renal region, these shadows must be distinguished from calculi.

4. **Osteoarthritis of the vertebrae.**—In cases of osteoarthritis of the vertebrae, they resemble ureteral calculi. They are a trifle nearer the spine than the normal course of the ureter, and the latter changes of the spine, such as hipping and destruction of the cartilages, are always present.

5. **Small calcareous bodies or so called phleboliths.**

#### Calculus.

Usually single and only on one side. If multiple they are arranged in lines which correspond with the course of the ureter, usually are irregular and have rough edges. If they are round, or small with rough edges, they change position between exposures with attacks of renal colic and blood in urine. They must be in line with the course of the ureter.

#### Calcified Bodies.

Calcified bodies near the lower end of the ureter usually are multiple and on both sides. When multiple they are arranged in a line running in the opposite direction to the course of the ureter. They are round with smooth edges and so small that were they calculi they would pass or change position between exposures. Usually they are one-quarter to three-quarters of an inch to the outer side of the ureter.

Ureteral catharization, which is discussed later, aids very materially in distinguishing between these conditions.

6. **Folds of intestines.**—These are not as well defined as calculi; usually seen only accompanied by accumulation of gas and appear as long, narrow shadows instead of the shape of calculi. Unless the fold is permanent and held in place by adhesions, it does not appear in confirmatory plates.

7 and 8. **Enteroliths and foreign bodies.**—Enteroliths and foreign bodies change their position. A Murphy button in the stomach viewed edgewise might readily be taken for a large calculus, but sooner or later it would show the hole in the centre.

9. **Calcified arteries.**—Calcified arteries usually are bilateral and show the tortuous course of the arteries, and are not in the position of the kidney or ureter. Whether the shadow shown in Fig. 12 is a single calcified plaque in an artery which shows indistinctly, or a true phlebolith in a vein, is undecided, but it is certain that it is not a calculus in the ureter.

10. **Calcified lymphoids.**—Calcified lymph glands, especially those in the pelvis, resemble calculi very much. They usually, however, are multiple and not in line with the normal course of the ureter.

11. **Prostatic calculi.**—Prostatic calculi are further down than ureteral or vascular calculi, and more closely resemble phleboliths.

12. **Finger marks.**—Finger marks made during the development of the plates might readily be mistaken for stone.

13. **Developing stains from uneven flood of developer.**—Irregular flooding of the plates during developing may leave a small area that resembles a stone.

14. **Flaws in plates.**—A slight flaw in a plate came as near causing me to make an error as anything I have seen. The case I have in mind, shown in Fig. 12, appeared as a small, well defined, round shadow with clear cut edges, exactly in the region of the kidney and about the place the patient had complained of the greatest pain. Up to this time I had only made confirmatory plates in doubtful cases, and this did not appear to be a doubtful case, but, fortunately, a confirmatory plate was made and the spot had disappeared. On closer study one could see it was a flaw in the plate.

15. **Tuberculous kidney.**—Some cases of tuber-

culous kidney may be very readily diagnosed by x ray, as shown in Fig. 13. In this case the entire kidney was involved with an old, slow tuberculous process. A radiograph made two years previous to this one was the first in which I felt justified in making such a diagnosis. It was later confirmed by the finding of tubercle bacilli, but the patient refused operation, and we are thus able to watch the development of the case by a series of radiographs. In another case the process was so distinct that it was difficult to distinguish between it and calculus, but as the treatment for each was the same the differential diagnosis was not so important.

16. Shot in back.—Shot in the muscles of the back are more distinct and the edges more clear cut than calculi.

17. Aside from these possible mistakes we find well defined permanent lesions which I have been unable to diagnose.

*X Ray versus Exploratory.*—Anyone who has hunted for a needle in a finger, even after a radiograph has shown its presence and apparently its exact position, realizes how difficult it is to find a foreign body. The finger is much smaller than the kidney, there is nothing to prevent cutting in all directions, hemorrhages may be prevented, and all the circumstances are most favorable, yet few persons except radiographers know how prolonged and unsuccessful operations for foreign bodies frequently are. How often you hear this phrase: "The x ray showed a stone, but none was found on operation." No one would question for a minute the fallacy of the exploratory operation, especially if the kidney was split and the calices explored with the finger. The following cases would show the relative value of x ray and exploratory incision:

The writer radiographed a patient, as shown in Fig. 14, and made a diagnosis of six calculi, a large one in the pelvis, and five small ones apparently in the calices. An operation was performed by a very careful surgeon, the kidney was split and the large stone was found. A thorough search was made by the surgeon and his assistant for the small ones. The calices were explored with the finger of each of the operators. Assuming that the nodules on the calculus were what I had interpreted as five small calculi, they informed me that the radiographic diagnosis of a large calculus was correct, but that there were no small ones present. About six weeks later the patient had a severe attack of renal colic and passed five of the largest calculi that could possibly pass. The large calculus was in such a position that the small ones could not possibly have slipped past into the ureter before or during the operation.

A number of cases are on record where the calculus had been shown in radiographs and not found on operation, but later the diagnosis has been verified by removal of the kidney, when the calculus has been found. Are surgeons justified in saying that the calculi are not present after an exploratory operation, when a satisfactory radiographic examination and positive diagnosis have been made?

*Catheterization versus X Ray in the Diagnosis of Renal and Ureteral Calculi.*—Comparing the relative value of catheterization and x ray, so much depends on the technique of the one and the dexterity with which the other is performed that we will only compare the results of the best of each. Each has its dangers.

In x ray there is the danger of the so called burn, but with the short exposures of thirty to fifty seconds this is practically eliminated. The danger of infection and shock from ureteral catheterization you are in a position to know better than I am, and the discomfort, to say the least, well—the patient is the best judge of that, and most of them have very decided views on this subject.

As to their value, each has its place. Many things can be determined with the catheter that cannot be with the x ray, but in the diagnosis of renal calculus, if you cannot find a stone in the kidney when it is split open by examining each calix with your finger, how do you expect to make a negative diagnosis of calculus at the other end of a catheter sixteen inches long? And with what certainty can one say that he touches a stone in the pelvis of the kidney? In the diagnosis of ureteral calculi the catheter is of more value than in renal, as one can say with certainty that he meets with an obstruction so far from the bladder, and with wax tips or other devices, in some cases may be reasonably sure it is a stone, but whether it is small or large, smooth or rough, and whether it will move or not, it is impossible to say.

A radiograph as reproduced in Fig. 15 will show the size, shape, and position of a calculus, and with a little experience one can tell whether it will pass or not. A small, rough one will lodge, while a smooth one of astonishing size will pass. On the other hand, small calcified bodies near the lower ends of the ureters, called by many phleboliths, are frequently mistaken for calculi. The characteristic differences between these are described early in this paper, but a combination of catheterization and x ray, as shown in Fig. 16, is of greatest value, using a stylet catheter and making a radiograph.

As I said, these phleboliths are usually about one half to three quarters of an inch to the outer side of the course of the ureter, but sometimes directly in line with the ureters, and in the x ray appear to lie against the catheter. It is wise to make two radiographs at different angles to prevent this source of error. The following cases will show the fallibility of making a negative diagnosis of ureteral calculus, even though the catheter passes all the way to the kidney with little or no obstruction.

CASE I.—The first case of ureteral calculus that I radiographed showed a well marked shadow at the lower end of the ureter, oval in shape and about one centimetre long. It appeared in several plates. Ureteral catheterization showed no obstruction at this point. An exploratory operation was performed and on palpation no calculus could be felt. The ureter was opened and a catheter was passed down into the bladder without meeting with an obstruction. At that time I was not familiar with so called phleboliths, and insisted there must be a calculus, so just before the wound was closed a further search was made and the calculus was found in a pocket it had formed in the ureter just before it passes into the bladder. It was pushed out of the pocket into the ureter and out of the opening near the kidney.

CASE II.—The second case was where a young woman was catheterized by one of the most eminent genitourinary surgeons in the country, with a wax tipped catheter, and the catheter was passed up to the kidney without obstruction, but with a scratch on the wax tip. Preparations were made for an operation, but an x ray failed to show the calculus in the kidney. The ureter was again catheterized and there was no obstruction in the matter of scratch on the wax tip of the catheter. The operation was indefinitely postponed and later the case was referred to me by

another surgeon. Fig. 5 shows very distinctly a calculus about one half inch in diameter near the lower end of the ureter. An operation verified the findings of the radiograph. The surgeon says the calculus passed from the kidney to the lower part of the ureter between the time of his last examination and my first. This, of course, I cannot disprove.

Considering the previous case and the following case which I am about to describe, it seems possible, at least, that the calculus was in the ureter and the catheter passed it with little or no obstruction.

CASE III.—The third case was referred by Dr. Bangs and Dr. Pederson, and their history of the case and record of operative procedure is as follows:

First attack of renal colic took place on July 12, 1907. It was severe on the right side; there was frequent vomiting; the pain was confined to right kidney region; no radiations; no bladder symptoms. Hematuria was not noted, perhaps because the patient did not look for it.

Second attack occurred the following day. It persisted for seven days with varying severity, some vomiting during first day. The pain remained localized as before.

For a month thereafter he suffered nagging pain every few days, lasting from a few seconds up to a few minutes.

Third attack happened on December 21, 1907. Very severe, no radiation.

Fourth attack took place on December 24; the pain ceased suddenly.

Fifth attack happened December 26th, and lasted from 10 p. m. until 5 a. m. Again the pain ceased suddenly.

Cystoscopy, performed on December 27th, showed no calculus in the bladder, and nothing distinctively pathological in its appearance.

Radiographic examination, December 28, 1907, showed two calculi (Fig. 17), one just below the brim of the pelvis and the other opposite the transverse processes of the fourth lumbar vertebra.

Cystoscopy and catheterization of right ureter was performed on January 8, 1908. No obstruction was encountered, no grating sensation was perceived.

Second radiographic examination, January 11, 1908, showed that the calculus, which was near the brim of the pelvis had descended to the lower end of the ureter, but that the upper one was in the same place, opposite the transverse processes of the fourth lumbar vertebra.

The lower stone was passed from the bladder, 11 a. m., January 12, 1908.

Cystoscopy and catheterization of right ureter performed on January 13th. Again no obstruction was felt. Patient was now free from all pain and tenderness over the right ureter.

Another attack of pain in the right kidney region, lasting ten minutes, during the night of February 24. Patient passed another almond shaped calculus similar in shape and size to the first calculus on February 11th. The patient when last seen (February 24th) had been entirely free from symptoms of any kind.

Radiographs of both calculi were made after he passed them, and these are reproduced in Fig. 17 with the first radiograph made of him.

These cases demonstrate that it is unwise to make a negative diagnosis of ureteral calculus, even if there is no obstruction in the ureter.

*Do Calculi Perforate or Migrate Through the Walls of the Ureter?*—The case just described, where a stone was found in a pocket near the lower end of the ureter and another case (Fig. 18), where a calculus was found to be imbedded in the walls of the ureter, seem to suggest this possibility, and Dr. Bryant told me of a case where a stone containing uric acid salts was found in the abdominal cavity. In another case the catheter met with obstruction about one and one half inches from the ureteral orifice. The case was radiographed at the patient's request to ascertain the size and shape of the mass and the possibility of its passage. The

calculus was shown at this point, but there was a well defined one in the kidney, which was verified on operating.

One of the most important points that the writer has to make is, that many of the cases having typical attacks of renal colic do not have a stone in any part of the genitourinary tract, and when a calculus is shown in this class of cases it is usually so small that it will pass without an operation other than ureteral catheterization.

On the other hand, most of the cases in which renal calculi have been demonstrated by x ray have had no symptoms that were sufficiently characteristic to justify an operation, and only those that engage in the ureter or obstruct the pelvis cause typical renal colic. They may have pain either in the back or side, especially on jolting or riding in a car, tenderness over the kidney, dull aching, or especially what is described by them as a sense of weight or heavy feeling in the back. Figs. 19 and 20 demonstrate this class of cases very clearly. Fig. 19 shows a large rectangular calculus in the pelvis of the right kidney, and Fig. 20 shows a calculus four inches long in the lower end of the right ureter of the same patient (in process of reproduction the plates are reversed, which causes it to appear on the left side), and yet the symptoms were not sufficient to designate which side the trouble was on. The patient had been treated for many months or a year for stomach trouble.

A great many of the cases diagnosed as lumbago or rheumatism of the back have renal calculi. Whether the calculus is the cause of the lumbago, or the lumbago the cause of the calculus, is not for me to decide.

Calculi giving symptoms of chronic appendicitis are very common. Several of the cases in which calculi have been demonstrated were diagnosed as appendicitis, and radiographs have been made just to eliminate the possibility of calculus. This has occurred in so many cases that some physicians are having nearly all cases of obscure abdominal lesions radiographed. The wisdom of this is particularly shown in the following cases:

CASE IV.—A woman, fifty years, complained of symptoms which were diagnosed as appendicitis (chronic). She traveled a great deal both in this country and abroad, and her hobby was to get the opinion of the best authorities in every country, and strange as it may seem, they nearly all agreed that it was appendicitis in some form or another. She finally came under the care of a physician who had many of his obscure abdominal lesions radiographed, particularly those of appendicitis, to distinguish them from renal calculi. This case, as shown in Fig. 7, had a stone at the pelvis of the kidney, and several appendicectomy had given no indication of stone.

Ten or eleven of the fifty-four cases in which I have demonstrated renal calculi have complained of all the pain, or the worst, same pain, on the opposite side from that on which the calculus was found. Fig. 21 shows one of these cases. This is such a peculiar fact, requiring a detailed history of each case to make it complete, that it seems unnecessary to incorporate it in this paper; I therefore merely mention it here to show the necessity of making radiographs of both sides.

Before making a positive or negative diagnosis of renal or ureteral calculi, much information may

be gained by a radiograph having sufficient detail to show the kidney distinctly. The density, shape, size, and position may help very materially in making the diagnosis of tuberculosis, new growth, pro-lapse, and congestion of the kidney, and ascertaining the presence of the kidney on the opposite side.

The kidney may be seen more or less distinctly in about 75 per cent. of the cases, and if special care in technique and selection of tubes is used, it may be shown in nearly every case. Strange as it may seem, the size of the patient has very little influence—indeed, in large, fat persons it is more frequently seen than in thin ones. This may be accounted for by difference in density between the kidney and fat it is imbedded in; the more fat the greater this difference is. The soft tissues of some patients are much more dense to the rays than others, and where this is so the kidney shows very distinctly compared with the spine, which in these cases shows indistinctly.

The repeated appearance of one kidney and not the other, or the increased density of one compared with the other, or with the psoas muscle, indicates a change in the kidney, and if this density is uniform, and the kidney is not mottled, it is due, probably, to congestion of that organ, as shown in Fig. 22. If the kidney appears mottled, as shown in Fig. 13, or of irregular density, it would indicate tuberculosis or new growth, and if the contour of the kidney is changed in addition to the irregularities of density and mottleness, it increases the probability of new growth. Several confirmatory plates are necessary, and these shadows must be differentiated from the same things calculi are, particularly fecal accumulations.

*Size.*—The size of the kidney compared with the opposite one may be fairly accurately determined, but it must be remembered that it is slightly enlarged in the radiographed. The amount of this depends on the distance of the x ray tube from the kidney, and the distance of the kidney from the plate. In a person of ordinary size, with the tube eighteen inches from the plate, the radiograph represents the kidney about one half to three quarters of an inch larger than it really is. In some cases the pelvis of the kidney and the ureter show distinctly, but it is doubtful if this is of any pathological significance unless it is thickened and irregular, which would indicate tuberculosis (Fig. 13).

The position of the kidney at the time the radiograph is made may be demonstrated very accurately if the position of the tube is considered. If the kidney is shown to be out of place, the diagnosis of floating kidney is positive, but if it is shown to be in its normal place it does not indicate that it is not movable, as the position of the patient, and particularly the pressure of the compression blend, tend to cause it to assume its normal position.

*Résumé.*—The principal points that should be remembered are:

With a limited knowledge of the science, radiographs have been made which did not have sufficient detail to justify a negative or positive diagnosis, and persons without sufficient experience have made negative or positive diagnosis on these plates.

The separation of the x ray into three varieties. The value of the direct in radiography and the detrimental effect of the indirect and secondary.

The interpretation of the plate is more important and more difficult than making it.

The amount of detail necessary for a negative diagnosis.

Technique, diet, clothing, catharsis, position, exposure, etc.

Necessity of making full set of plates.

Reasons for believing that one is justified in making a negative diagnosis of calculus when detail as described is present.

Things calculi must be distinguished from.

X ray versus exploratory examination in the diagnosis of calculi.

X ray versus ureteral catheterization in the diagnosis of calculi.

Most patients having typical attacks of renal colic do not have stones, and, on the other hand, only very few of the patients who have calculi have symptoms sufficiently characteristic to justify an operation.

Similarity of symptoms of chronic appendicitis and renal or ureteral calculi.

About one quarter of the patients in whom calculi are found have the most pain on the opposite side.

Value of the x ray in the diagnosis of tuberculosis, new growths, and nephropotosis.

One cannot expect any great amount of success in renal radiography when work requiring so much attention to detail is turned over to hospital orderlies, nurses, even physicians without any training or experience along this line.

103 PARK AVENUE.

## A CASE OF CHRONIC FIBRINOUS BRONCHITIS.\*

By E. BURVILL-HOLMES, M. D.,  
Philadelphia,

EX-ASSISTANT Chief Resident Physician of the Municipal Hospital;  
Bacteriologist of the Henry Phipps Institute.

Acute or chronic inflammatory conditions of the bronchial mucous membrane, accompanied by expectoration of casts of the bronchial tree, are of comparative infrequency, and in consequence such cases are always of interest. In the past thirty-eight years one hundred and eleven cases of this disease have been recorded in the literature. Of this number one hundred—including two of his own cases—Bettman (1) in an exhaustive article thoroughly analyzed. Since Bettman's treatise appeared up until the end of the past year, eleven additional cases have been reported, viz.: by Vassal (2), Rabe (3), Shoyer (4), Moser (5), Schwarzkooff (6), Deganello (7), Bosc (8), Bilina (9), Giglio (10), and Dehon and Brasser (11). Contributions to the subject have been made by Eiselt (12), who enters upon the etiology of the disease, Milian (13), and Rabé (14).

Vassal's case was one complicated with exophthalmic goitre in a woman of thirty-five years. Bron-

\*Read, by invitation, before the College of Physicians, Philadelphia, February 10, 1908.

chial casts showing arborescences were expectorated. A man of thirty-seven years was the victim in a case reported by Rabe. In this case it followed closely in the wake of a pneumonia and terminated fatally about three weeks subsequent to the initial onset. In Shoyer's case the patient was a man of seventy-four years, who, in early adolescence, had had tuberculosis and who, five days after the onset of what was diagnosed influenza, coughed up a complete cast of the bronchus 10.5 cm. long. For three weeks after, he expectorated great quantities of ribbon like strips of fibrin. He was entirely well in one month.

Moser believed syphilis to be the ætiological factor in his case, a man of forty-eight years who had recurring attacks of severe coughing and dyspnea. The sputum was blood stained and in it casts of the bronchi were noted. Fifteen years previously he had had a chancre, and at the time of the attack had syphilitic manifestations such as ocular palsy, dermatitis, and myocarditis.

Schwarzkoﬀ reports a case of a girl, thirteen years of age, whose mother was tuberculous. The patient had undergone four attacks of acute rheumatism which were followed by some cardiac disturbance, but she had never had any severe bronchial or pulmonary disease. For three years she had had a slight chronic cough, occasional hæmoptysis, and subsequently typical attacks of fibrinous bronchitis. Tuberculosis as an ætiological factor was absolutely excluded, and Schwarzkoﬀ believes the cause was mitral insufficiency.

The cases of the remaining six authors I am unfortunately unable to recite owing to the fact that the necessary journals were not available at the library.

The case which was referred to me by Dr. Ross T. Skillern and to whom I am indebted for the privilege of reporting is as follows:

The patient was a young lady of twenty-six years, whose family history was absolutely negative. Her past history was good, as aside from measles, varicella, scarlet fever, and pertussis in childhood she had always been well. Her menstrual function was normal. The trouble which prompted her to seek medical aid first made itself apparent about eight weeks ago by a short, hacking, unproductive cough, which was particularly troublesome at night and in the morning upon rising. About one week after the onset she was seized with a violent paroxysm of coughing and of such a nature that she imagined she was again developing whooping cough. The paroxysm continued for several minutes, and only ceased when a large "piece of phlegm," as she thought and expressed it, was dislodged and expectorated. Prior to this paroxysm there was no dyspnea and she was not in any sense of the word ill. A few days later, just how many the patient did not recollect, and again in the morning, a second paroxysm occurred and another large piece of "phlegm" expectorated. A third and a fourth occurred at intervals of from four to seven days, always in the morning, and relief from it always brought about by the dislodgement and expectoration of a large, greyish white, solid piece of material. She stated that she could always appreciate that there was something within her lung that ought not to be there; that this something was always felt in the same place, and that place just under the clavicle of the right side. In her own words "she felt as if by putting her two fingers in her throat she could drag out the offending material."

After her last paroxysm she noticed that what she expectorated had some definite form and was undoubtedly something more than mere bronchial secretion, so she preserved the specimen and with it visited her physician. As this patient had at the same time, to the physician's knowledge,

been a host for lumbricoids, he concluded upon superficial examination of the specimen that she had vomited rather than coughed up one of these parasites. Hæmoptysis had never occurred, she never had night sweats, appetite was and always had been fair, there had been no loss of weight, and all her body functions had been regular. Indeed, aside from the chronic dry cough, associated at intervals with the paroxysms mentioned, she never felt the least bit ill. As far as she knew she has never had an asthmatic attack.

Physical examination of the patient showed a fairly well nourished and developed girl of somewhat anæmic aspect, and very nervous, her nervous state depending, however, probably on the fact that it had been hinted to her that her condition might be one of tuberculosis, a statement which she was the more ready to accept since she appreciated how closely she had associated during the summer with an intimate girl friend who recently died at the Whitehaven Sanatorium.

Careful examination of her chest showed a decided limitation of movement in the upper right side anteriorly compared with that of the left. Over this area, too, the breath sounds were appreciably weaker than those of the opposite side. There was apparently no impairment of resonance anywhere, and no râles could be heard. Her heart was normal, and the other organs apparently so.

A specimen of her sputum, which was difficult to obtain, inasmuch as she expectorated but little, showed nothing of moment. No tubercle bacilli were found. A bacteriological study of a washed specimen showed the streptococcus and the *Staphylococcus aureus*.

Milian, in a contribution on the subject of fibrinous bronchitis, divides bronchial casts into four classes, namely: Bacterial casts, which are very rare and composed almost entirely of organisms; mucous casts, also very rare; fibrino-leucocytic casts, and lastly blood casts. The cast from this patient was of the fibrino-leucocytic variety, but differing from Milian's description, who says in regard to the cellular elements, "*bien colorés, c'est-à-dire bien vivants, rarement mortifiés*"—in that many of the cells show degeneration. The most interesting histological feature, however, was that the cellular elements were largely composed of eosinophiles, which, according to most of the writers, are found only in small numbers. On the other hand, mono-nuclear leucocytes, which are as a general thing to be noted in considerable numbers, were in this specimen conspicuous by their sparsity. Stained by Weigert's method, the stratified anastomosing substance in the meshes of which the leucocytes were, showed for the most part to be composed probably of mucin, although a little fibrin was present. Several sections stained for the ordinary pathogenic bacteria showed none of these, which was again interesting, since these can usually be identified, except, as Rabe points out, in old exudates. A large number of sections were examined for the tubercle bacillus, but were, to the exclusion of a single one, unfruitful of success. This one section, however, did show what very strongly resembled three acid fast bacilli, but inasmuch as several were examined without result, and as the sputum, as we have seen, was negative, it would be unjust in view of this indefinite ocular evidence to positively diagnose them as such. Cultures from the cast were not made, as I thought the results would be of little value, since the specimen had been kept for some time in an unsterile bottle.

Macroscopically the main trunk of the cast was about five centimetres long by about four millimetres in diameter. It terminated in two branches, each about twenty-five by three millimetres. This is, of course, when compared to those reported by other authors, which averaged ten to sixteen centimetres, not a large one. No lumen could be recognized in either the main trunk or its branches. The cast was of a slate color.

Bettman, in analyzing a hundred cases, classified them as follows: 1. Chronic bronchitis with expectoration of branching casts; 2. Acute bronchitis with expectoration of branching casts; 3. Cases in which branching casts were not expectorated but found at autopsy; 4. Cases in which cast showed dichotomous branching; 5. Expectoration of casts in organic heart disease; 6. Expectoration of casts in pulmonary tuberculosis; 7. Cases of small and non-

branching casts associated with asthma; and 8, formation of casts in bronchi, in cases of pulmonary oedema following thoracentesis.

Accepting this classification then this case would belong to either the category of group 1, viz., the expectoration of branching casts associated with chronic bronchitis, or to cases in group 6, cases associated with pulmonary tuberculosis. If to the latter the case is interesting because in the cases recorded by Jacoud, Model, Duflocq, and Ménétrier the expectoration of casts did not occur until late in the disease, and consequently with clinical symptoms well marked. However here, while we have much to substantiate the inference of probable tuberculous trouble, namely the circumstantial evidence of close association for three months with a rapidly dying case of consumption, suspicious physical signs, the markedly diminished movement of the upper right chest with weakened breath sounds over the same area; a lymphocytosis in the circulating blood, and opsonic index of 0.7, and lastly the finding in one of the sections what suspiciously resembled acid fast bacilli, it is by no means definite. At best the subjective and the objective symptoms are such that if tuberculosis exists at all it is in its incipency, and hence if the ætiological factor in this case, the case is rare.

Comparing the case with those associated with chronic bronchitis it presents one or two interesting features. Usually these cases exhibit marked dyspnoea preceding the expectoration of the cast. This patient says that she never had dyspnoea, and having none it is exceptional for the severe paroxysms of coughing which she suffered from, because observers have noted that in those cases in which dyspnoea does not obtain, little or no coughing is the rule. As is usually the case the casts were always formed in the one place, as is evidenced by the patient's own appreciation of their location. The not uncommon symptom of emaciation and loss of strength is not present here. The patient weighed 136 pounds and she said that she never weighed more than 140. No skin complications such as pemphigus, impetigo, or herpes zoster, noted by many authors in connection with these cases, existed, or as far as I could ascertain had existed.

#### ACCIDENTS DURING ANÆSTHESIA.

*Their Recognition, Prevention, and Treatment.*

By E. R. ZEMP, B. S., M. D.,

Knoxville, Tenn.,

Professor of Materia Medica, Therapeutics, Pediatrics, and Clinical Medicine, Tennessee Medical College.

Death from an anæsthetic is such an appalling event, and carries with it such a stigma in the eyes of the public, that any research that has for its intention the lessening of the dangers pertaining to this class of drugs should receive the careful attention of all who are called upon from time to time to administer them. It is true that comparatively few patients die from the direct effect of an anæsthetic, but this apparent safety makes anæsthesia more dangerous. A physician does not need more than one death from this cause to injure him seriously in his community. The public seems to think that all deaths from this cause are due to carelessness or ignorance, and in some cases, no doubt, this is true. There seems to be an opinion among medical men that anybody can give an anæsthetic, so often we see the cone in the hands of medical students, and even the laity are intrusted with it. The mortality from anæsthesia will never be lowered by putting its administration into the hands of inexperienced and ignorant persons, but this practice will be the means of teaching some doctor some day a very severe lesson.

There is so much to be said upon this subject that one is at a loss where to begin, but believing that an ounce of prevention is worth many times its weight in cures, I will begin by briefly stating some of the points we should observe, when it is possible, in preparing the patient to receive the anæsthetic. Some of these may seem very trifling to the dogmatic, superficial eye, but each detail goes to make up the whole ideal, and it is only by striving to attain the ideal that we are able to obtain the best results.

When it is practical, the patient should have several days' attention before the operation; better, a week. Chemical and microscopical examinations of the urine should be made. The bowels should be emptied, which takes several days of careful purging. However, no purgative should be given later than forty-eight hours before the operation, but an enema should be given about twelve hours before the appointed time. The free administration of water by the mouth is very beneficial, and both combine to limit the formation of gas, thereby reducing intraabdominal pressure. The food should be carefully regulated for several days, the most easily digested food being selected. Nothing should be given in the way of food twelve hours before the operation, as the nervous state of the patient inhibits digestion. If conditions permit, a general bath should be given the night before the operation, and it is also highly important that the patient should get a good night's sleep preceding the day appointed for the operation. Hypnotics should be used, if necessary, and there is perhaps none better than trional (sulphonethylmethane). All of these points bear directly upon the patient's safety. When carried out they give the patient the very best chance of taking the anæsthetic quietly and safely.

for such preparation means that you have put the system in the very best possible condition. In minor operations it is, of course, unnecessary to go into such an elaborate preparation of the patient, especially where the anæsthesia is to be of short duration, but even in these cases such a preparation could do no harm.

Before the patient is brought to the anæsthetizing room a careful examination of the heart should be made. Note the color of the skin, the character of the pulse, the condition of the arteries, whether they are hard or soft. The character of the respiration should be noted, as should also the patient's general temperament.

All rings having been removed from the fingers and ears; all loose teeth having been taken out; all constrictions of throat and chest having been corrected, the patient is brought to the table and is ready for the anæsthetic. It is a good plan to give, a few minutes before the anæsthetic is begun,  $\frac{1}{8}$  grain of morphine and 1-150 grain of atropine. This quiets the patient and reduces the excitability of the respiratory tract. It does more than this. It lessens the excitability of the inhibitory centre of the heart, which centre is very wide awake during the early stages of anæsthesia. It steadies up the vasomotor system and thereby lessens the fall of arterial pressure, so certain to occur under chloroform. It diminishes the amount of mucus secreted under ether, thereby lessening the chances of an infected respiratory tract, pneumonia. The position of the patient is important. He should be flat on his back, with only a small pillow under his head and shoulders. The arms at the beginning should be in such a position so that the fingers can be clasped over the abdomen. Do not be in too much of a hurry to begin the anæsthetic. Converse with the patient cheerfully. Allay his fright as far as possible. Assure him that he will be safely carried through the trying ordeal. Death has occurred a number of times from fright alone, even before a drop of the anæsthetic had been given, so it is best to divert the patient's mind from himself as much as possible. The best way to do this is to have the patient put the ends of his thumbs together and press firmly upon them. I say to them: "The more queer you feel the harder you press." This concentrates the mind upon the thumbs and gives the patient something to do, which is much easier than trying to be perfectly passive. Whatever you do, do not tell the patient to take a deep breath. This is just what you do not want him to do. You want him to be as "natural" as it is possible to get him. Now begin the anæsthetic—chloroform, we will say. Drop by drop it should be added, not to one spot on the mask, but all over it. The wire frame covered with several layers of gauze is the best mask for either chloroform or ether. Some authorities say, push the anæsthetic as soon as the higher centres show signs of incoordination, but it is best never to push it, in the sense of adding a large amount of it to the mask at one time. The continuous dropping will, in the large majority of cases, silently and surely do the work. So easily do many patients take chloroform in this way that if one is not careful the surgical stage will be passed before one knows it, and the patient will be in that stage of complete

relaxation that is hardly ever to be desired. No matter how carefully the anæsthetic is given, very frequently symptoms will arise that call for either more anæsthetic or its immediate withdrawal; consequently it is important to understand all the phenomena that may arise, that we may avoid danger on the one hand or the needless allowing of the patient to come from under the anæsthetic on the other. No anæsthetizer can forget the disgust that mounts the surgeon's face when a patient is allowed to wake up in the midst of a difficult operation unnecessarily.

Generally the first difficulty we strike is some abnormality in the breathing, commonly stertor. There are three kinds of stertor: Palatine, mucous, and pharyngeal. The first two are not danger signals, but the last calls for the immediate removal of the mask. It is caused by the tongue dropping back against the posterior pharyngeal wall, and if not attended to the patient may suddenly suck his tongue tightly down into his throat, thus cutting off the air entirely. It is a sign of marked relaxation, which is always dangerous ground to be on. We remedy this condition by temporarily removing the anæsthetic and bringing the chin forward and up. This pulls the tongue away from the posterior wall and permits the air to enter. The palatine stertor may be remedied in the same way. When lifting the chin forward and up does not relieve the condition promptly, the tongue itself should be caught with forceps or napkin covered fingers and gently pulled forward and up, toward the nose. Pulling the tongue straight out over the teeth only makes the condition worse. After the tongue has been pulled away from the posterior pharyngeal wall it can generally be kept away by keeping the chin well up and the patient's mouth shut, or by turning the head to one side, so that gravity will carry the tongue in this direction rather than backward. After the stertor is relieved the anæsthetic may be continued. Sometimes there appears quite early a choking sensation, and the patient will try to remove the mask. This should be met by the administration of a little air, after which the anæsthetic can be dropped somewhat faster. The following conditions indicate that the anæsthetic should be gradually increased: Marked lateral rolling of the eyes, deep, sighing respiration, swallowing, hiccough, and vomiting. During the last mentioned event the patient's head should be immediately turned to one side, to prevent the vomited matter from being aspirated into the lungs. It can be stated as a safe rule to follow that if the respiration at any time becomes irregular the anæsthetic should be suspended, for it is by the respiration that we can best judge the amount of anæsthetic the patient is getting. Even in the early stages, where irregularity in the respiration is known to be of reflex origin, it is best to admit a little air before increasing the anæsthetic. When struggling, holding the breath, or vomiting occurs, alarming symptoms may suddenly develop, so that one should deal gently with these symptoms. Beware of the inspiratory "whoop." On several occasions I have had patients stop breathing after giving this whoop, and they were revived with the greatest difficulty. The mucous stertor so frequently heard when ether is being admin-

ministered is due to an outpouring of mucus and saliva. If very excessive it can be removed with a piece of gauze wrapped around the finger, or, better still, by turning the head to one side, thereby draining the patient's mouth. The so called "pumping method" of getting rid of the mucus requires some skill and will be used only by the expert anesthetist. In this method the patient's chin is pressed downward and backward during expiration. This forces the mucus out through the nose. During inspiration the chin is held in its usual position—forward and upward.

Should the anesthetist watch the pulse or the respiration? I believe he should watch both, but he should especially watch the respiration, noting the pulse from time to time. If the patient is getting too much anæsthetic, this fact will be reflected in the respiration, either by change in rhythm or depth. Under chloroform, with its accompanying low arterial pressure, the temporal or even the radial pulse is not a true index to the heart's action. The respiratory centre is quick to notice any marked fall in the pressure, because under such circumstances it is not properly supplied with blood; hence we will get a disturbance of the respiration before we can appreciate with the fingers on the pulse that there has been a dangerous lowering of arterial pressure. Another point to be remembered is that the amount of anæsthetic a patient is getting cannot be judged by the amount we pour upon the mask. It is the amount that he inhales that regulates the effect. When the respiration becomes irregular the dose becomes uncertain, and when the dose becomes uncertain the patient is in danger. So we watch the respiration to see if the patient is getting the anæsthetic in evenly distributed doses. It is the sudden increase of the percentage of the anæsthetic in the blood that usually kills the patient. It matters not whether we watch the respiration or the heart, we are unable to forecast these sudden deaths that sometimes arise, especially from chloroform, but in the ordinarily healthy heart watching the respiration will enable us to judge how well the patient is standing the anæsthetic. The patient's face is a good index to the respiratory movement. Marked cyanosis means respiratory failure. Pallor indicates heart failure.

A slight irregularity in the heart's rhythm has no special significance. Neither do murmurs necessarily contraindicate the administration of an anæsthetic. Especially is this true if there is no distinct functional disorder. As Dr. Wood says, the key to the situation is not found in the valvular lesion, but in the condition of the heart muscle. Loud murmurs do not more strongly contraindicate an anæsthetic than do weak ones. The very loudness of the murmur shows that the heart muscle is in a fair condition. It is a safe statement to make, however, that anæsthetics should be avoided, if possible, in all diseased conditions of the heart, bearing in mind that the shock of the operation without an anæsthetic may be more dangerous to the patient than the anæsthetic. Every anesthetizer has noticed how the weak, nervous heart is improved by the anæsthetic. The vasomotor system being depressed, a patient gets chilled if the proper care is not taken

to keep the temperature up, but it is doubtful whether this chilling is ever a cause of the post-operative pneumonia that follows the administration of ether.

The wise selection of the anæsthetic will diminish the liability to accidents. All forms of organic brain diseases contraindicate the administration of anæsthetics, especially if there is atheroma of the vessels. In this case chloroform would be the anæsthetic of choice. Without atheroma, ether is safer. In heart disease, without complications, ether is the anæsthetic of choice. Where there is pulmonary engorgement, all anæsthetics are very dangerous. The combined use of chloroform and ether is perhaps the best plan under these circumstances. In chronic lung troubles chloroform is safer than ether. In all acute pulmonary affections, especially if associated with dyspnoea, anæsthetics are strongly contraindicated. The same is true in obstructive laryngeal diseases, but chloroform is less dangerous than ether. In spasmodic laryngeal troubles chloroform should be selected.

In kidney disease authorities differ in regard to the selection of the anæsthetic, but I believe the majority of them lean toward chloroform as the anæsthetic of choice. Our selection, however, would be influenced by the secondary effect of the disease. If the heart was markedly affected, ether would be our choice. If the lungs were engorged, chloroform would be safer, as ether would increase the engorgement.

The time of day would influence our choice. Ether is inflammable, so it should be used cautiously in the presence of a light other than the incandescent electric. It should be remembered, however, that while chloroform is not inflammable, it undergoes degeneration in the presence of a flame and chlorine is liberated, causing a severe irritation of the respiratory tract to all in the room.

In spite of all the care we can bestow upon the patient, alarming symptoms and sometimes death will occur. There is no method known to man of administering an anæsthetic that is entirely free from danger. Beware of the anesthetist whose own peculiar method of administration has banished the hypodermatic needle from the operating room and reduced the mortality from anæsthesia to nothing! Eternal vigilance should be the watchword, and the minute the least suspicious symptom arises the anæsthetic should be suspended. Death may come suddenly. Alarming symptoms may arise at any time.

How can we tell when the patient is in danger? First, by closely watching the respiration. Any irregularity means trouble. Watch the face for cyanosis or pallidity. Examine the pupils from time to time; their sudden dilatation without fluctuation means stop the anæsthetic and give plenty of fresh air. Note the pulse from time to time. A weak, fast pulse calls for stimulation and the momentary stopping of the anæsthetic.

Suppose, however, instead of any of these symptoms, the patient suddenly shows signs of impending death. What is to be done? First, don't get excited. Have a systematic plan of treatment "at your fingers' ends," then apply it speedily but thoroughly. Unless the heart is beating forcibly, which

is entirely unlikely, invert the patient's body to an angle of forty-five degrees with the floor. Immediately begin artificial respiration and see that the tongue is held in such a position, by an assistant, that the air can enter the lungs freely. This is lung washing, and is the only way we can get the poison (anæsthetic) out of the patient, just as we wash out the stomach when the patient has swallowed a poison. Artificial respiration should be faithfully and persistently carried out. The patient must be made to breathe. The rhythmical dilation of the rectum is a powerful stimulant to the respiration. It rarely fails to make the patient gasp. Pressure over the abdomen while the patient is inverted will help to send the blood to the brain, where it is so badly needed at this time. As for drugs, only two or three are of any value, and these should be given hypodermatically: Strychnine sulphate, 1/10 grain, and digitalis, 5 minims, should be administered by an assistant. Ammonia may be inhaled, and a pint of decinormal salt solution, containing fifteen or twenty drops of adrenalin chloride solution, may be given under the skin. This sometimes has a markedly restorative effect. It should be borne in mind, however, that absorption is exceedingly slow in these cases, on account of the defective circulation, so that in administering drugs toxic doses should not be given, nor should the doses be repeated too often or too close together, for drugs given under these circumstances remain under the skin just where they are injected until the circulation begins to improve, at which time all of the doses may be absorbed at once, killing the patient. Artificial respiration stands first; all other restorative measures are secondary. Be sure to provide plenty of pure air and keep the patient warm. After the patient has recovered he should be watched for several hours. There are certain drugs that have been used in treating impending death from anæsthesia that I regard as of doubtful efficacy, if not actually dangerous. Amyl nitrite is one of these. This drug depresses in a powerful manner the entire central nervous system, including all the higher centres. It paralyzes the vasomotor system in large doses and depresses the heart. I will admit that there is a time in its action when it apparently stimulates the heart, but this occurs only when the dose is regulated to a nicety, and is exceedingly fleeting. "The dominant action of amyl nitrite is that of a powerful depressant to all higher forms of protoplasm," and especially is this effect noted upon the vasomotor system. Alcohol in any form is also contraindicated, for it only differs in that its action is more prolonged. Especially is this true when ether is the anæsthetic. Hypodermatic injection of brandy or whiskey should not be given. The hypodermatic injection of ether is a physiological outrage. Nitroglycerin acts similar to amyl nitrite.

The writer hopes that this paper will aid these physicians who are called upon from time to time to administer anæsthetics. With a careful attention to its details many of the unpleasant symptoms of anæsthesia can be avoided and its dangers greatly diminished.

617 WALNUT STREET.

## ON THE ÆTIOLOGY OF PSORIASIS.

BY BERNARD LE ROY, M. D.,  
Athens, Ohio.

The causes of psoriasis are not known. This is the gist of the writings of the authorities on skin diseases, as it is the first statement of nearly all lecturers when presenting cases of psoriasis to the class.

It was while the writer was taking a prolonged course of instruction in laboratory methods and technique at the Philadelphia Polyclinic Laboratories that the idea first came to him to try out the method which has proved successful in growing the germ which, when the opsonins were made therefrom and used in treatment upon the patient, resulted in a speedy and safe cure of the disease.

I had been attending the clinic of Professor Schamberg for the purpose of gathering material for laboratory use when he presented a very bad case of psoriasis. During his lecture he spoke of the aggravating effects that hot water and soap had upon this disease. Perhaps it was because of the way he put this information to the class, nevertheless it impressed me forcibly and I became determined to try out the method which came to my mind during those moments. I intended to have made the trial then and there, but was called home, and it was not until this winter that an opportunity presented in which I could do so.

But first let me quote from some authority on skin diseases—and perhaps Hyde on the *Diseases of the Skin* is as good as any—to show us the present state of the bacteriological search for the cause of this dreadful disease.

"Lang, of Innsbruck, attracted notice by his alleged discovery of certain fungous elements in psoriasis that he asserted to be the cause of the disease. These fungi he finds in the whitish pellicle beneath the superficial squamous layer, to which Bulky had already called attention. After stripping the pellicle or a part of it from the surface, and subjecting it to the action of a five per cent. solution of caustic potash, the epithelium appears translucent, and upon and beneath the epithelium double contoured and highly refractive spores become visible. Lang considers this fungus to be of the lowest species, different from any previously recognized upon the skin, and he terms it *epidermophyton*. Weyl, who believes that psoriasis is due to 'an inherited weakness of the nervous centres,' has seen Lang's 'brood cells,' and he regards them as 'myelin like exudations'; but this position is disputed by both Wolff and Eklund, who confirm Lang's observations, and who believe the disease to be of parasitic origin. Lassar succeeded in producing a disease of the skin in rabbits by rubbing into various portions of their bodies scales, blood, and lymph removed from psoriatic patches of a male patient."

I could quote from other writers, but to the same effect, that nothing definitely is known.

The case upon which I determined to carry out the mental suggestion received during Professor Schamberg's lecture was a man aged forty-eight, short and stolidly built, in excellent health, other than being afflicted with psoriasis on one of the lower limbs. He was a man of an ever careful and regular in all his habits, and he has never been sick, nor had any disease since early childhood.

The patches were numerous and thick, extending from the lower part of the leg, to the knee, and were of a brownish color, and have a scaly surface. The patches were of the size of the palm of the hand, and the patient had been using the only cure of his kind, from time to time.

As I examined this man the words of Professor Schamberg came to me, with the same force and

mental pictures received while at his clinic one year ago.

I proceeded to work by removing the outer scales, and when I had reached the lower stratum I proceeded with care and removed scales to a wet slide, keeping the scales moist with soapy water and at a temperature of 104° F., examining it at stated intervals with the high power lens. At the end of twelve hours I failed to detect any change whatever in the scale, the "myelin like exudations" were in evidence and seemed to so fill the scale that nothing else could be seen.

I left it that night under arrangements whereby the moisture and temperature would be retained at even degree. The next morning I was surprised to find that the temperature stood at 190.4° F., scales moist, and upon examination I was surprised to find a growth of a very peculiar germ; all the "myelin like exudations" were in bloom, and the growth was at or from one end of the spore, looking for the world like a transparent, delicate, diminutive stove pipe placed over one end of an egg.

In the hanging drop I found that while the organism is in this state it will swim through the fluid, spore end first; after the growth of the vegetative end has reached an almost fully developed state the organism will swim or move through the fluid vegetative end first. Now one may see the germ making strong and rapid movements to rid itself of the spore. Should it succeed it will move away as an independent organism, but should it not become free and not be disturbed it will develop into as pretty growth of fungus as could be found.

The bottom growths, grown in a liquid medium containing sodium nitrite, are of a long, slender, delicate, transparent nature, containing comparatively few spores, while the top growth seems to run to seed, so numerous are the spores. In one organism I was able to count over sixty spores.

I then made a liquid medium, slightly alkaline, and containing 0.1 per cent. sodium nitrite, and securing fresh scales, as before, I incubated at 159° F. for two weeks in semidarkness. The growth was heavy, and examinations from time to time showed the same odd shaped and odd acting germ.

I at last succeeded in obtaining a pure culture, from which I made the opsonins, and gave the patient his first treatment. The opsonic index was taken several times, but proved nothing.

I have not finished my study of this organism, but suffice it to say that it is a mould.

At the end of four days my patient reported at my laboratory and seemed none the worse for the treatment. The reaction, while quite severe for about twelve hours, simulated rheumatism or a slight cold settled throughout the muscular system; the patient never lost a meal nor an hour's time during the course of the treatment. The only change noticeable was a pitting of all the scales, as if each scale was punctured with fine needles; this was noticed in every part of his body.

At the end of eight days he reported again. The pitted condition of the scales was still in evidence, with a decided lessening in the amount of the scales formed on the inflamed patches of integument.

The second treatment was given; the reaction proved to be of less severe character than the first.

In ten days he again reported. There was now

noted a decided change in the color of the inflamed skin, changing from a bright red to a dull leaden red, a decided shrinking in the elevation of the inflamed integument, with numerous patches of shrunken areas of smooth surface, which seemed to be on a level with the normal integument. This was the first noticeable change toward a return of the psoriatic patches to a normal condition.

After the fifth dose the case progressed without a stop or hitch in a smooth and even way toward full recovery and a permanent cure; at least, I have good reasons to so state.

I have several milder cases under treatment at this time, which I shall report later.

In conclusion it may be of interest to some to know that in the examination of the saliva the sulphocyanides were present, and that the content of ammonia was above the normal, while the basic salt of the saliva was potassium, and, as it is in all inflammatory diseases, the secretions from the parotid glands were in less amount than that from the other salivary glands, causing the saliva to be of a thick, stringy and frothy nature.

I have made a chemical study of this organism and its opsonin, as I have of that germ which I have made use of in my study of the epilepsies and allied paralysis, and have found the same reaction or substances which give the same reactions in both germs, being found in greater quantities in the nidus fluid, or liquid medium, in which the organism was permitted to grow, until, from the accumulation of a certain crystallizable substance (which is an anti-enzyme), prevents the organism from performing its normal function, thus causing its death. It is this substance, and not phagocytosis, as is now believed, that is the active agent in producing immunity.

There are found three distinct crystallizable substances, each forming distinct and different, though beautiful, crystals, and an amorphous substance, which I have reasons to believe is composed of two different substances.

So far my laboratory studies have shown me that each of these substances have distinct physiological actions. One is the toxine which affects the host, the second is the autogermicidal toxine which I know will, when in sufficient strength in the body, kill the germ, and from laboratory experiments believe it to be an antiferment. The other substances, as well as those just mentioned, are still being studied, with prospects of a full report within the year.

#### ON THE MANAGEMENT OF TYPHOID FEVER WITHOUT A NURSE.

BY L. C. FREENY, M. D.,  
Pittsville, Md.

The average general practitioner is obliged to treat probably three fourths of his cases without the help of a trained nurse. Now and then one comes in contact with people of good habits of observation who make capital nurses, never having had any experience in the handling of the sick. On the other hand, those you might expect to do good work are often the most disappointing.

After some years of experience, I have made out a sheet of instructions for the use of the family

when a competent nurse is not available. This sheet I have typewritten, and order it to be tacked on the wall. The family are told that when a question arises, if they will read the sheet carefully they will in all likelihood find in it just what they want to know, as it covers a great deal of ground.

It may be as well to state that as soon as the diagnosis is made full directions as to the disposal of fæces, urine, and sputum are gone into thoroughly, once for all. Also the disinfection of the bed linen. A solution for the disinfection of the hands is kept in the room all the time, with the warning that it must be used to prevent the disease being communicated to those in attendance.

There are set aside for the patient's own use a sufficient number of glasses. These are scalded after being used each time, and once each day the whole number is boiled in a solution of sodium carbonate. The same precautions are taken with the china, spoons, etc., at a later time, i. e., when the patient is convalescent.

A member of the family is shown how to take the pulse, respiration, and temperature. These are put down in a schedule, together with the number of bowel movements and approximate amount of urine day by day. From this data I fill out the chart myself for my own guidance in the case and for future reference.

I sponge an arm to show how I want it done, rubbing the part rather briskly with a dry cloth. Then the arm is "slushed" with 95 per cent. alcohol. Some will not agree with this manner of sponging, but it gives a more thorough refrigerant effect than without friction. Not only that, but it keeps the skin in good condition, stimulates the patient, and quiets the nervous system, the patient falling into a quiet and refreshing sleep.

If the family will carefully follow out the scheme, and watch the patient closely, notifying the physician of any untoward symptoms, many of the accidents in the management of this disease will be avoided. To many that will read this it will seem foolish or childish, but the patient's friends will not think so. They fully understand that they are undertaking something that they are unfamiliar with, and anything that helps them in this self imposed task will be gladly accepted.

#### *Some Things to Remember.*

Sponge the patient every three hours when the temperature reaches 102.5° F. or over, unless he is in a sweat. Use a watch to time yourself when sponging, and make it take you at least thirty minutes to complete it.

Do not sponge the patient when he is in a sweat, but wait, even if the temperature is high, until the skin is dry and hot, before sponging.

Take the temperature every three hours.

Give the nourishment every three hours.

If you forget the medicine don't forget the nourishment and the temperature.

Watch every bowel movement for any sign of blood.

Report to me any complaint of pain in the bowels.

The nourishment ordered is enough. The patient must not have anything else.

Keep quiet in the room and always encourage the patient.

Give a warm soapsuds bath every morning at 9 o'clock, and an alcohol rub every evening at 9 o'clock.

Never rub the abdomen at all.

Write down anything of importance that you may want to ask me; then it will not be forgotten.

#### CHLOROSIS CURED BY THYROID EXTRACT.

By F. K. MACMURROUGH, M. D.,  
New York.

CASE. B. H., aged twenty-two years, female, single, occupation bookkeeper, suffered with symptoms of chlorosis since first menstruation. Fainting spells, heart flutterings, constipation, scanty menstruation, and constant leucorrhœa were the more prominent troubles in this case. The blood count was deficient. The treatment consisted of thyroid extract, 3 grains after meals, a daily quart clyster of normal salt solution, Bland's pills, the practice of deep breathing, and open air life. All the symptoms yielded which had before been intractable to other modes of treatment. The remedial measures employed were suggested by a cursory reading of the second volume of Sajous's *Internal Secretions* and the *Principles of Medicine*.

If we are henceforth to ascribe many, if not all, diseased conditions to overstimulation or depression of the pituitary bodies and the consequent effect upon the internal secretions of the ductless glands, viz., the adrenals, thymus, parathyroids, thyroids, and the spleen, medicine becomes at once an exact and a simplified science. That such is the case Sajous, in his exhaustive treatise on the *Internal Secretions*, seems very strongly to establish. He traces the nerve connection between these ductless organs and the pituitaries so clearly, and shows the control exercised by that portion of the brain over the oxidation of tissue or tissue respiration, the internal secretions acting and counteracting on the blood through the "ferment of ferments," that the vista at once gladdens the heart of the therapist and brings an air of the fact accomplished which becomes the most reassuring and convincing thing in latter day medicine.

Following Sajous's line of medication, the two contrasted conditions of exophthalmus and myxœdema would give the key to the whole subject. Sajous says in the preface to his second volume that he does not introduce any new theory or speculation in medicine. He has simply followed such men as Brown-Séquard, Langlois, and Ciliulski. He does not even introduce a new serum. He simply introduces order where there is a certain medical disarray. Mercury, iodine, quinine, strychnine, opium, and the bromides have, through his good offices, come into their rights, and rank higher than before in the list of medicaments. Thyroid extract is, perhaps, placed above them, but they are all congeners, and henceforth may become, in the hands of the profession, weapons of as much point and precision as the needle or the sterilized blade. At the same time he delivers a death blow to self medication at the hands of the laity, for when this new step in medicine is realized and grasped by the public mind, a proper dread should be felt by all for the unscientific treatment of disease. Every man should then not be his own physician any more than every man is now his own surgeon.

## Our Readers' Discussions.

### A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far they have been decided upon, the further questions are as follows:

LXXXIII. How do you treat seasickness? (Closed April 15, 1908.)

LXXXIV. How do you treat sunstroke? (Answers due not later than May 15, 1908.)

LXXXV. How do you treat cholera infantum? (Answers due not later than June 15, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisors will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL.

The prize of \$25 for the best essay submitted in answer to question LXXXII has been awarded to Dr. J. Russell Verbruycke, of New York, whose article appears below.

### PRIZE QUESTION NO. LXXXII.

#### THE TREATMENT OF FRACTURE OF THE PATELLA.

By J. RUSSELL VERBRUYCKE, M. D.,  
New York.

House Physician to the Mt. Sinai Hospital (Private Pavilion).

Perhaps in no other injury does the future usefulness of the part depend so much upon proper treatment as in fracture of the patella. In spite of all our efforts, the result is often far from perfect, and usually the patient has some weakness of the leg, particularly in extension, though perhaps flexion, also, may be restricted. More unfavorable outcomes, such as nonunion or insufficient fibrous union and bony ankylosis, are far too common.

The natural tendency of the fragments, because of their usual wide separation, is to heal by fibrous union. This must be prevented, and an attempt made to obtain bony union, by more perfect coaptation of the fragments. The separation is produced by the retraction of the strong quadriceps muscle, the collection of a large amount of fluid exudate and blood, which generally takes place speedily after the injury, and the interposition between the fragments of the torn periosteum or aponeurosis. The prognosis is governed in great measure by the presence or absence of these factors and the consequent treatment employed.

#### Simple Fractures.

Eighty per cent. of simple fractures of the patella are transverse. The aponeurosis covering the patella is usually torn, while the capsule and reinforcing tendons of the vastus internus to the inner side and the prolongation of the fascia lata on the outer side may also be injured to greater or less degree. The extent to which these are injured has an important bearing in the prognosis and treatment

of the case. There are two general methods of treatment: (1) By mechanical means, and (2) by open operation. In cases of transverse fracture, in which there is not much injury to the surrounding parts, no interposition of soft parts, not too great swelling, and the fragments can be brought into good apposition, the mechanical treatment may be relied upon.

The best device is probably Agnew's. Use a splint of board, about thirty inches long, five inches wide at the top, and four inches at the lower end, having two pegs projecting laterally from each edge, the upper peg on each side to be above the patella and the other two below. After padding well apply it to the posterior surface of the thigh and leg, and elevate the lower end. Bring the fragments into position by strips of adhesive, of which one passes from the upper peg on one side, downward, under the lower fragment, thence to the upper peg on the other side, while the other strip is passed from the lower peg on one side, upward, above the upper fragment, and thence to the lower peg on the other side. By this means the fragments are pulled toward each other, and by turning the pegs more pressure may be exerted at will, so as to keep them approximated.

Since, however, the mechanical treatment often gives fibrous and incomplete union or the continued immobility tends to produce bony ankylosis, mechanical treatment has its disadvantages. One can never say when there is an interposition of soft parts between the fragments, and cannot always estimate the probable extent of the tear in the surrounding structures.

So what appears the more ideal method of treatment, now that nearly perfect asepsis can be obtained, is the open operation and wiring. This is the only method by which bony union can usually be obtained. A longitudinal or transverse incision is made over the fracture, and the exudate, hæmorrhage, and tabs of tissue thoroughly cleaned out of the joint. It is preferable to wash the joint out with hot, sterile salt solution from a nozzle, and the fingers should not touch the parts any more than is positively necessary, all handling being done with instruments as far as possible. The fragments are brought together and held in position by two silver wire sutures passed through holes bored obliquely through the dorsal surface and edge of each fragment. The torn periosteum is united with heavy catgut, the tear in the lateral expansion of the tendon with kangaroo tendon, and the wound closed. A posterior splint is applied. As soon as the skin wound has healed, and the sutures have been removed, the knee is encased in a light plaster of Paris cast. This is split in a few days, and removed every day to allow light massage of the joint. In three weeks the patient, still wearing the cast, may walk with crutches, and in a month passive motion should be practised. The cast should be worn during the day for three months.

Good results with bony union are obtained by this method in about ninety-five per cent. of the cases, while the operation itself has scarcely any mortality in the hands of good operators. It is the ideal method of treatment, but should be employed only

where the conditions are such that an absolutely aseptic operation can be performed, and by a competent surgeon.

Longitudinal fractures require little treatment. The fragments do not tend to separate widely, and may be held in place by adhesive strips and the use of a posterior splint for two weeks, after which the patient may walk with the knee in a light plaster cast for several more weeks. The same may be said of fissure fracture and most cases of oblique fracture. If the fragments tend to separate in an oblique fracture, treat as a transverse fracture. T shaped fractures should be wired.

#### *Compound Fractures.*

Of course, it is evident that the open method, with removal of small fragments and thorough cleansing of the joint, followed by approximation with sutures, is the treatment which must be followed in this class of cases. Temporary drainage should be instituted. Heavy chromic gut is preferable to silver wire in these cases for holding the fragments in apposition, as, in the event of infection taking place, the gut is absorbed, while the wire remains as an irritant, preventing healing, until removed.

#### *Summary.*

1. In simple transverse fractures, when the proper facilities are at hand, the results are more sure by open method and wiring, with a consequent bony union.
2. If the patient objects, or operation is not feasible, results from the Agnew splint are next most satisfactory, though followed more often by fibrous union.
3. In other varieties of simple fracture, the treatment depends on the amount of separation, approximation being usually easily obtained by adhesive plaster and the use of a splint.
4. All compound fractures should be treated by approximation of fragments with heavy chromic gut instead of silver wire, and the use of temporary drainage.

*Dr. Walter Ennis Hays, of New York, writes:*

We base our treatment of any condition requiring medical or surgical attention on our understanding of the morbid process presenting itself. The usual thing in fracture of the patella is to find a varying degree of separation of the fragments. Especially is this the case when there has been quite an extensive laceration of the soft tissues. The fractured surface of the upper fragment is tilted toward the cavity of the knee joint by the pull of the fibres of the vastus externus and vastus internus inserted into the outer edge of the bone. The traction exerted on the upper fragment by the tendon of the quadriceps extensor and a counter pull on the lower fragment by the patellar tendon serve to separate the two fragments, the prepatellar tissues then falling over the edge of the upper fragment and interfering with direct apposition of the fractured surfaces. A tension within the joint due to trauma of the synovial membrane also separates the fragments, the inner edge of the distal piece of bone being usually tilted outward. There are cases of fracture of the patella with little injury to the soft tissues

and but slight separation of the fragments. These cases offer good results from conservative or non-operative treatment. Fibrous union of the injured bone, with its final crippling of the patient to a greater or less degree, is so much to be dreaded, however, that the radical treatment is always to be preferred where a competent surgeon and the strictest aseptic technique can be assured.

The patient should be frankly informed as to the dangers of sepsis with the risk to life and limb, as well as the expected advantages to be derived by the operative method. The probable results of the conservative treatment should also be laid before him. The working man or any one else actively using his legs can expect a shorter convalescence and a probable better result by the operative than by the expectant treatment. Operation should never be attempted in individuals of over sixty years of age, and is, of course, always necessary in compound fractures. In multiple or comminuted fractures, operation is also indicated, and wiring of the fragments should be done. Amputation may have to be considered in the latter class of cases. Preliminary treatment of the joint to reduce swelling may be necessary. The foot is elevated and the joint immobilized. The ice bag and cooling lotions are applied to limit the inflammatory reaction. A flannel roller bandage, reapplied as necessary, will greatly aid in the absorption of the effusion. As soon as the inflammation has subsided, operation may be attempted with better result.

The operative treatment consists in careful cleansing and sterilization of the area about the knee joint with soap and water, alcohol, ether, and corrosive sublimate solution (1 in 1,000). A transverse or longitudinal incision is then made exposing the cavity of the knee joint. All blood clots and shreds of tissue must be wiped away from the surfaces of the fractured bone and the joint cavity sponged or irrigated free of clots or other tissue debris. If the joint is irrigated, sterile normal salt solution should be used, except in an open fracture, where mercuric chloride solution (1 in 10,000) may be employed and followed by the salt solution. Care must be taken to reach all parts of the joint, especially posteriorly, behind the condyles of the femur. It is usually not necessary to fasten the bony fragments unless the fracture is an old one or comminuted, as mentioned before, and difficulty is experienced in retaining the injured bone in proper position. The ligamentous tissue covering the patella is sutured with chromicized catgut, after the fractured surfaces have been carefully approximated. The fascia is also brought together with chromicized catgut, while the skin is closed with a subcuticular suture of silkworm gut. No drainage is necessary. The joint is then immobilized in a posterior wire or plaster of Paris splint. Massage may be begun after two weeks. At the end of three weeks, passive movements should be instituted. A week later the splint should be removed, and a light stiff dressing applied about the knee joint. The patient should then be encouraged to attempt walking. At the end of the sixth or eighth week the patient should be able to flex the knee, and will only need to wear a light flannel bandage, and no brace. A month later the splint should be removed as before the accident.

In the conservative method of treatment the knee joint should be immobilized by a posterior splint, either of wire or board with side pieces, or of plaster of Paris. The latter has seemed more satisfactory, as it can be perfectly fitted about two thirds of the circumference of the leg from the gluteal furrow to the foot. Several layers of cotton flannel, well rubbed up in cream of plaster of Paris, can be applied posteriorly to the leg, and held in place by a muslin roller bandage. It may be removed as necessary and reapplied. Care should be taken that it should fit snugly after the joint swelling has disappeared. Adhesive plaster strips are used to approximate the two fragments in proper position. One strip of the plaster is applied from above downward obliquely about the joint, so that its lower edge will pass over the upper border of the upper fragment of bone, pulling it downward and preventing the inward tilting of its lower edge. A second strip is passed obliquely from below upward and posteriorly over the lower fragment, so that the outward tilting of its fractured edge will be obviated. Occasionally it will be necessary to firmly apply a strip of adhesive transversely about the joint to prevent eversion of the fractured edges. By traction and countertraction thus exerted to promote apposition of the fractured surfaces, firm fibrous union can often be secured and a good result follow. As the effusion disappears, readjustment of the adhesive plaster strips will be necessary. After the first week, daily massage of the quadriceps extensor should be done, without removing the splint, to prevent atrophy through disuse. At the expiration of three weeks the splint should be removed daily, and massage and passive movements practised. At the sixth week, a light stiff splint should be applied and walking with crutches permitted. After the eighth week, active motion may be tried with care, the crutches discarded, and a cane used. This light stiff splint about the joint should be continued until the sixth month, when a flannel bandage should be applied and employed for three months longer. After the ninth month a support is not usually required.

Comparison of results from the two methods of treatment shows to the credit of the radical or operative in more perfect restoration of function, better bony union, and a shorter invalidism. However, the danger from sepsis must not be discounted, even with complete facilities for cleanly work.

*Dr. P. C. Hutton, of the United States Army, states:*

In the treatment of a fractured patella we first seek an accurate reduction and means to immobilize the fragments. Accurate reduction is dependent largely upon the time elapsing between receipt of injury and the time the patient is seen by the surgeon. If seen immediately, the swelling will not be such as to prohibit approximation and retention of fragments, but if seen after the effusion has become prominent steps must be taken to dissipate this effusion before reduction can be accomplished. An elastic bandage, should other means not be at hand, will ordinarily secure the desired results, if traumatism has not been very severe, in twenty-four hours or less, but two flat sponges, about the size of a man's hand, are equally efficacious and more com-

fortable to the patient. These sponges should be applied after the joint is snugly wrapped in a flannel bandage and in such a manner that the sides of the sponges come together over the anterior surface of the patella. After carefully applying the bandage, which holds them in position, with such force as may be consistent, hot water (115° F.) is slowly poured over the whole until the sponges become saturated. This process is repeated each hour until the bandages and sponges are removed.

Having dissipated the effusion, the leg is massaged and the fragments approximated. The lower fragment is drawn upward as far as practicable, and there maintained by a strip of adhesive plaster, one and one half inches wide, passing beneath the lower border, encircling the leg obliquely, and overlapping on the under surface in the popliteal space. The injured member is now elevated by an assistant, and the upper fragment brought downward into apposition in a similar manner, the adhesive plaster overlapping on the posterior surface at about the lower border of the knee joint. A properly padded, long posterior splint is affixed and held firmly by straps, preferably made of canvas, and attached to back of splint with a buckle, so situated as not to infringe upon the limb. Of these straps there should be four, one at each extremity of the splint and one above and one below the knee. In addition to fixation of leg to splint these straps also serve to prohibit powerful contraction of the extensor muscles. This prohibition is more completely realized, however, when coaptation splints are also applied over the lower half or two thirds of the quadriceps, but before their application a second strip of adhesive plaster is passed above and below the respective fragments, and the extremities of the straps made fast to the posterior surface of the splint in the oblique manner as indicated. As the swelling subsides these straps may have to be tightened. In this event the fragment is held in position by an assistant while the surgeon reapplies the strap. The limb is now bandaged snugly to the splint, both above and below the knee, the joint being left clear for inspection and examination. The limb should then be elevated in order to secure relaxation of the extensor muscles.

The treatment from this point onward is of the greatest importance, and the result attained will depend largely upon the manner in which the case is handled after reduction is complete. Daily massage, beginning upon receipt of injury, must be carefully and systematically employed. The external bandaging having been removed, the masseur should begin at the ankle and slowly work upward. In massaging the joint care must be exercised that no violent friction is developed. The tips of the fingers only should be employed at this point. Union takes place in from two to six weeks, depending somewhat upon the age of the patient, and the splint should not be removed until the latter time has elapsed. In this statement I am not unmindful of what certain books recommend on this subject, but having once had a distasteful experience I am in no position to advise the removal of the cast nor the commencement of passive motion at the end of four weeks. The only danger of waiting six weeks is that of partial ankylosis, and this always clears under massage and passive motion. It is much better

to have a well united patella than to have one weakened by passive motion practised upon fibrous shreds before union is complete. Therefore at the end of six weeks passive motion is to be instituted and the massage still continued. At this time, also, a removable, light plaster cast may be employed, and at the end of eight weeks the patient allowed to walk on crutches. About the tenth week the crutches may be abandoned for a stout cane. The light splint is worn for four to six months, when it gives way to a flannel bandage, and in the meantime the massage is continued. It is best to continue the flannel bandage for one or, perhaps, two months, when it may be removed. At this time perfect function should obtain, but the patient is to be cautioned to avoid quick movements and the sudden application of weight to the injured limb for a period of one to two years.

*Dr. Walter Lathrop, of Hazleton, Pa., says:*

While fractures of the patella are not common as compared with those occurring in other bones, yet the importance of correct treatment cannot be overestimated, as the correct or incorrect handling of the case usually determines the usefulness of the limb.

The cause of these injuries is usually direct violence, and in my experience has most frequently happened to railroad brakemen, who have been struck by a brake iron, while setting or releasing a brake. Again, I have seen it due to a kick from the point of a heavy shoe. It may also be caused by sudden contraction of the muscles or flexing of knee. Of course a fall against some solid material would easily produce the injury.

Most of my own cases have been of the comminuted type, and I believe those produced by direct violence are frequently of this order, while muscular contraction would tend to give a single break, and this is usually transverse, and below the middle.

The symptoms, while familiar to all, may be briefly stated in order of importance as, sudden loss of power, pain, great swelling about the parts, and difficulty in raising the limb from the bed. There is also a characteristic hollow between the fragments when the leg is bent, and often with no moving of limb we can separate the parts easily.

In regard to treatment we have to consider the conditions present in this class of cases. We have a joint filled with blood; we have the fragments pulled apart, and kept so by the action of a powerful muscle and tendon, and we have also the strong supposition that interposed between these fragments are pieces of tissue or shreds of aponeurosis, which will act against our getting bony union if allowed to take a course of nonoperation. It is true that in many cases nonoperative treatment will give, and has given, good results so far as fairly good use of the limb is secured, provided the treatment has been most carefully and thoroughly applied when the injury is first received.

In the nonoperative treatment we hope to achieve several things: The removal of effusion in joint and tissues, and to overcome muscular opposition are the chief objects in view.

The application of cold compresses is most valuable, accompanied by firm bandaging, or we may

remove fluid by aspiration or small incision, being sure of having the parts surgically clean. After removal by incision or tapping, the part should be firmly bandaged, to prevent a return of the trouble. The treatment of the fracture is best done, I believe, by the use of the Agnew splint, with or without the adjusting pegs; my preference is either a firm figure of 8 bandage, bringing the bones together as well as possible, or else using strips of adhesive plaster, carefully applied, and passing beneath the splint.

Plaster of Paris for fixation I have abandoned entirely in these cases until several weeks have passed, when the limb may be put up in plaster, and patient let up on crutches, and shortly after the cast may be removed, and massage, passive movements, and gradual use of the knee be commenced.

In regard to operative treatment, I am convinced by a fairly large experience that, under strict surgical cleanliness, aseptic or antiseptic surroundings, fair ability, and clean work on the part of the surgeon, this method offers the very best of all measures, in securing bony union, and a useful limb. When a patient is elderly, or in poor health, I think it better not to operate, although possibly a local anæsthetic might be used, but I doubt its expediency.

We must remember also that opening the knee joint is not a simple affair, but a formidable operation, to be undertaken with the same preparation that would be used in opening the abdomen, and, in fact, the after results are more often in doubt where the knee is involved than where the abdomen is concerned.

Stiffness of the limb, infection, and possible loss of the leg are possibilities not to be ignored, and it is therefore self evident that the chief element of success in these cases is scrupulous cleanliness at every stage of the operation. If we can place the injured parts in practically the same position as they were before the injury, then we should expect a practical cure, and it can be secured by the method which is described in this paper, and used by a good many surgeons, and is most satisfactory in the results obtained.

The leg and knee are carefully prepared for operation, and then an incision made either across the joint from side to side, above the fracture (my custom), or a "U" shaped flap turned up, exposing the parts beneath. The torn tissues about the fracture are turned back, all clots and debris carefully and thoroughly removed by sterile salt solution, aided by forceps if necessary. The leg is then extended and held firmly while the fragments are brought into apposition (care being taken to prevent any foreign matter from lodging between the bones), and sutures of chromic gut passed through the ligaments and tissues about the patella, as well as the periosteum, which should be secured over the line of fracture very carefully. The quadriceps tendon should be sutured with care, and the skin wound closed with silk worm gut or any suture of choice. I do not believe in the use of wire or nonabsorbable material, and my experience has proved it unnecessary. A loop of catgut may be passed entirely around the patella if the surgeon deems it necessary, but I seldom, if ever, use it. The after treatment consists in putting the limb on an Agnew splint.

with absolute rest, for two weeks; then very gentle manipulation of the patella only, and after four to six weeks passive motion, massage, and the gradual use of the limb, aided, of course, by crutches. Of course at the time of operation a small drain of gauze or horsehair may be inserted at the angles of wound if deemed advisable, but where hæmorrhage has been carefully arrested, and the suturing done with great care, the use of drainage is not often required.

As to time of operation, my practice is to operate at once if possible, before the advent of great swelling and hæmorrhage about the joint, but most of the patients have been received from two to four days after the accident, and I have always operated upon them at once, carefully cleansing the joint as before mentioned, and getting splendid results in every case.

I have tried the direct suture by wire, through holes drilled in the fragments, by passing wire around the fragments, and by a combination of methods, but none equal, or even approach, the means I have advocated.

*Summary.*—In elderly or feeble people the non-operative method seems advisable, save in selected cases. For the general practitioner the nonoperative is best.

Where hospital facilities can be obtained the operative method is much the better method.

Where good surgical skill is at hand this method is to be chosen in most cases. The use of chromic gut is better than nonabsorbent sutures. The great secret of success is absolute cleanliness, careful technique, perfect apposition, with all bleeding checked, absolute rest for ten days to two weeks, gentle massage after two or three weeks, and then passive motion, and gradual use of the leg.

(To be continued.)

## Correspondence.

### LETTER FROM HAMILTON, CANADA.

*The Ontario Medical Association.*

HAMILTON, April 20, 1908.

The twenty-eighth annual meeting of the Ontario Medical Association will be held in the Normal College Building, Hamilton, on the 26th, 27th, and 28th of May, 1908, under the presidency of Dr. Ingersoll Olmsted, of that city, the general secretary being Dr. Charles P. Lusk, of Toronto. A programme of great scientific and practical interest has been prepared; in fact, it is one which has not been surpassed by any medical organization in Canada within recent years. The address in medicine is to be delivered by Dr. Charles G. Stockton, of Buffalo; the address in surgery by Dr. Charles L. Scudder, of Boston. In addition to these, papers are to be presented by several eminent United States and Canadian physicians and surgeons. Among others are Dr. Virgil P. Gibney, of New York; Dr. Harry C. Buswell, of Buffalo; Dr. Thomas McCrae, of Baltimore; Dr. Lewis G. Cole, of New York; Dr. Benson P. Cohoe, of Baltimore; Dr. Harry P. Lyle, of New York; Dr. J. C. Meakins, of New York; Dr. Herman Sanderson, of Detroit; Dr. George E. Armstrong, of Montreal; Dr. A. E. Garrow, of

Montreal; Dr. J. W. Stirling, of Montreal; Dr. Campbell Howard, of Montreal; Dr. Colin K. Russell, of Montreal; Dr. Adam H. Wright, of Toronto; Dr. N. A. Powell, of Toronto; Dr. L. W. Cockburn, of Hamilton; Dr. J. C. Connell, of Kingston; Dr. J. T. Fotheringham, Dr. A. Primrose, Dr. W. P. Caven, and Dr. E. E. King, of Toronto. The meeting will convene in the following sections: General Medicine; General Surgery; Obstetrics and Pædiatrics; Eye, Ear, Nose, and Throat; and Preventive Medicine. The evenings will be given over entirely to the social side of the convention. On the first evening there will be a smoking concert at the Yacht Club at Hamilton Beach; on the second the annual dinner at the Royal Hotel, when the invited visitors will be the guests of the Hamilton members of the association. The entire afternoon of the second day will be given over to the business of the association, which is an exceptionally wise choice, as there are matters of importance to be properly presented and discussed which will be far better handled than if they were left to the last session, which in former years has been the case. The principal item of business at this session will be the reception of the report of the special committee of the association appointed to revise the constitution and by-laws to conform with the national medical body, the Canadian Medical Association, so as to provide for affiliation with that body. The splendid and attractive programme and the important items of business, combined with the promising social side, will be sure to induce many to attend, and the meeting will most probably be a record breaker in the history of the association. The Ontario Medical Association in the past has not traveled much. Most of its annual meetings have been held in Toronto. This departure will be watched with interest, and it is "up to" the profession throughout the province to support Hamilton to an unlimited extent. The popularity of the president and the hospitable inter-provincial spirit displayed in inviting many Montreal men to present papers to the meeting will contribute a due quota to the success of the meeting.

## Therapeutical Notes.

### Lotion for Gouty Joints.—

Sodium carbonate, .....	3iii.
Liniment of belladonna, .....	5i.
Tincture of opium, .....	3ii.
Distilled water, .....	℥i. q. s. ad 5℥ii.

M.

A small portion of the lotion is mixed with an equal quantity of hot water and applied on cotton to the affected joint. Repeat every four hours.

### Bismuth Subnitrate in Diseases of the Stomach.

—The *Archives des maladies de l'appareil digestif* contains a full account, by Gaston Lion, of the use of bismuth for diseases of the stomach. He insists upon the use of a very pure preparation in order to avoid toxic symptoms. The heavy subnitrate is to be preferred to the light, because the latter very often contains impurities, such as the carbonate or the oxides (*The Practitioner*, April, 1908). Chemically pure bismuth subnitrate is harmless, as much as  $\frac{1}{2}$ ss having been taken daily. Its use is indicated in gastric pain, whatever may be the cause, and is

equally successful in hypopepsia, aepsia, and hyperpepsia. It soothes gastric pains of all sorts, but is ineffective in those due to nervous dyspepsia. The sedative effects are produced from the second to the sixth day. In simple ulcer, it relieves pain and hastens healing. In cancer of the stomach, only temporary relief is afforded. In bleeding from the stomach, Lion confirms the good effects already noted by Mouneret and Fleiner. It acts as an antiseptic in abnormal fermentations. There is only one contraindication to the use of bismuth in large doses, which is when, in some part of the alimentary canal, stenosis exists. In these cases, bismuth accumulates behind the obstruction forming a concretion with the mucus. If used in cases presenting only a slight degree of stenosis, it must be given in small doses, and be watched very carefully. Constipation is no bar to its use, for large doses make the motions more regular, and may even produce diarrhœa. Lion is of opinion that it has a double action on the stomach; physically, by coating the mucous membrane, and thus shielding the glands and nerve endings from the more or less irritating effects of the gastric contents, ulcers being protected in the same way and healing promoted. Chemically, many believe that the salt is not acted upon by the gastric juice, but Lion, as the result of clinical examinations of gastric chemistry, has come to the opposite conclusion. He finds that bismuth, taken either before or with a test meal, lessens hyperchlorhydria, decreases the pepsin, and reduces the energetic action of the process of digestion. When it is taken with a meal, digestion goes on more quickly, and the stomach empties itself in a shorter time. Bismuth has no direct action upon secretion. It may be given in the morning, after lavage, in a dose of 5iiss to 5vj suspended in 5vj to 5viij of water. The patient should then lie down on the side corresponding with the presumed site of the lesion. When the protective action of bismuth is wanted, the dose should be given when the stomach is empty, and may be administered by the mouth. By giving a large dose five or six hours after a meal, the contents of the stomach are changed into a solution which is, though acid, not irritant, and the stomach then empties itself with ease.

#### Treatment of Symptomatic Urticaria in Infants.

—Schmitt (*Therapeutische Monatshefte: The Practitioner*, April, 1908), as the result of several years' experience, finds that the way to relieve the pruritus in strophulus or erythematous urticaria (which he prefers to term symptomatic urticaria) is to apply to the skin a five per cent. aqueous solution of ichthyol, to which should be added five per cent. of glycérine. This is applied twice a day, and covered with starch powder. More obstinate patches are treated by a coating of the following preparation:

R	Ichthyol, .....	5i
	Pulverized starch, .....	5â 3i
	White of egg, .....	5i
	Water, .....	5iv

M.

In the reflex forms, like that arising from irritation of the emptying teeth, which may be given internally, a young infant being able to take, three times a day, ten drops of a ten per cent. aqueous solution. There is not, as a rule, any definite shown

for the drug by children, disagreeable as it appears to adults.

**Treatment of Morphine Addiction.**—In the *Medical Record* for April 11, 1908, C. C. Langsdorf publishes a statement regarding the drugs used by him in the treatment of morphine addiction. The following are the formulæ employed:

#### I.

R	Compound extract of colocynth, .....	gr. i;
	Extract of hyoscyamus, .....	gr. 12;
	Extract of nux vomica, .....	gr. 1/2;
	Extract of jalap, .....	gr. 12;
	Podophyllin, .....	gr. 1/6;
	Oleoresin of ginger, .....	gr. 1/8;
	Calomel, .....	gr. 1.

Mix, and make one pill.

#### II.

R	Pills of pilocarpine hydr. chloride, .....	gr. 1;
	Fluid extract of hyoscyamus, .....	5iii;
	Fluid extract of prickly ash, .....	5iii;
	Tincture of belladonna root, .....	5iv.

M.

Dose: Seven to twenty drops every hour.

#### III.

R	Tincture of gelsemium, .....	5ss;
---	------------------------------	------

Dose: Five to twenty drops every two hours.

#### IV.

R	Tincture of strophanthus, .....	5ss;
	Tincture of nux vomica, .....	5i;
	Tincture of convallaria, .....	5ii;
	Tincture of cactus grandiflora, .....	5ii;
	Tincture of digitalis, .....	5iii.

Dose: Seven to eight drops every four or five hours.

Langsdorf lays stress on careful observance of details in administration. The usual dose of the accustomed drug [the addiction] is to be given at bedtime, along with three pills (Formula No. 1). In the morning, after free movement of the bowels, give another dose of the accustomed drug. If the bowels have failed to move, give a hot water enema or a saline laxative. Within one hour after the morning dose of the accustomed drug, give ten to fifteen drops of Formula No. 2, and continue giving No. 2 every hour. Twelve hours after commencing No. 2 start giving Formula No. 3, about twelve drops every two hours. When No. 2 has been given for fourteen hours, give three pills (Formula No. 1); continue No. 2 and No. 3. After No. 1 has acted freely, give a moderate dose of the accustomed drug. Continue No. 2, but stop No. 3 for eight hours after the last dose of the accustomed drug, then resume No. 3 as before. Twelve hours after the last dose of the accustomed drug give three pills (Formula No. 1) and when these have acted freely and show greenish or yellowish discharges, discontinue Nos. 1, 2, and 3 and start with Formula No. 4, about eight drops every four or five hours. Continue this for several days. When greenish or yellowish discharges appear the cure is effected. Should the patient become nervous or restless, give twenty-five drops of Formula No. 3. If the bowels are slow, assist with a saline, hot water enema, or castor oil. If, about the time for the last dose of Formula No. 1 to act, the patient becomes nauseated, give plenty of warm water and induce vomiting; it will give relief. If aching of the bones occurs, give a hot bath. If sleep does not come by the second night, give bromides or trional. Watch the pulse throughout the treatment.

transportation through the mail as second class matter.

NEW YORK, SATURDAY, APRIL 25, 1908.

CONSUMPTION IN THE TENEMENT  
HOUSES.

The work of combating pulmonary tuberculous disease among dwellers in the tenement houses of New York has been materially aided by the Charity Organization Society, which has recently published a summary of its twenty months' experience in collaboration with the Health Department and various city dispensaries. So far as the resources of these organizations would allow, all possible means of alleviating the condition of the sufferers and their families have been resorted to. Naturally, there has been but little expectation of actually curing the disease, except in its incipency, but even in this respect the results have been such as to contribute perceptibly toward lowering the death rate.

But it is not by the cure or arrest of consumption in the individual case alone that we must estimate the beneficence of the work undertaken by the society and its coadjutors. It is a great thing to prevent the spread of infection from the sick person to the other members of the family, and this the society has succeeded in doing in a notable number of instances. Instruction as to the disposition of sputum has, of course, been given, but this instruction has been most efficiently supplemented by material aid; in many instances in which the sick person was sharing his bed with another the society has provided bedstead and bedding for his sole use. Furthermore—and this is in the highest degree important—wages lost by reason of physical incapacity

for work, partial or complete, have been made good in money; families have been moved from insalubrious tenements to improved quarters, the society paying the increase of rent, or even, in some instances, the entire rent; nutritious food, clothing, and needed furniture have been supplied; sufferers have been sent into the country and maintained there at the society's expense; medical supervision, medicines, and nursing have been furnished gratuitously; and light work has been secured for those whose working capacity has been partly regained or not yet wholly lost.

Encouraging statistical tables are given in the pamphlet issued by the society, but mere figures can give but a feeble idea of the amount of good it has done, and it has all been accomplished with an expenditure of only about \$20,000 a year. This, however, consumed the whole fund which the society had at its disposal for the purpose, all derived from individual contributions. Such contributions ought to be greatly magnified, for in no other way that we can imagine is it now possible to fight urban tuberculous disease more effectively than by just such measures as the society has employed. It is a substantial gain to the community whenever an afflicted family is rescued from the lapse into pauperism and put in the way of retrieving its independence, and these things have resulted from the society's work in many an instance. We hope that its resources will soon be so augmented as to enable it to extend its beneficent activities to the utmost of New York's needs.

THE PREVENTION OF THE ORIENTAL  
PLAGUE.

Even for American readers the question of combating plague possesses more than academic interest, for the disease has obtained a foothold in San Francisco and has also recently been reported from Seattle. It is, of course, well established that it is spread through the agency of infected rats and the fleas which infest these animals. When this fact was discovered, it was believed to point the way for the ready suppression of the disease, but these hopes have not been realized. An interesting review of the question is presented by Professor W. M. Haffkine in the February number of the *Journal of the Royal Institute of Public Health*. According to this observer, the part played by man in the causation of plague seems to be subordinate to that of other agents. When plague first broke out in Bombay, in 1896, it remained for a considerable time confined to one quarter of the city inhabited by day laborers. Although these people spent considerable time in close communion with other people, the cases con-

tinued to occur only among the laborers and their families. Only subsequently and gradually did the disease appear in other parts of the town. Haffkine cites a series of such instances, and concludes that the plague is, in general, a disease of locality, that it is contracted principally at night, and that the part which man plays as a direct agent in its propagation is a subordinate one. So far as concerns seeking to combat plague by disinfecting or destroying infected merchandise, furniture, houses, etc., the item of expense and other difficulties are very great.

In discussing the measures directed to the lower animals, the following plans have been pursued: 1. Destruction or keeping away of rats by poisoning, trapping, tar and sulphuric acid mixture, or the agency of the domestic cat. 2. Improvements in towns and villages with a view of reducing or keeping out the rat population, viz., demolition of dwellings, storehouses, and insanitary buildings, prompt disposal of garbage, cleaning and draining of streets, etc. 3. Destruction and dispersion of fleas by petroleum or other insecticides. 4. Fumigation of houses as a temporary protection against rats and fleas. 5. Anchoring infected ships away from shore, or providing mechanical arrangements for preventing the landing of rats along mooring cables and gangways. 6. Fumigation of ships arriving with plague patients or plague rats on board.

Professor Haffkine gives a very interesting account of the campaign which has been waged against rats and fleas in various countries. It is admitted that such a campaign is the most rational and best founded of all the measures suggested for stamping out the plague, but it is important to estimate the extent to which this is a promising direction. The experience of the health officer of New South Wales is cited. This officer carefully organized a campaign against rats in Sydney, with the object of protecting from plague a white population of a high standard of intelligence and education. During the campaign it was found that the gross returns of rats and mice caught and destroyed week by week were nearly uniform, and that there was thus no evidence that the slaughter produced such an impression on the general horde as would have rendered collection progressively more difficult. The use of Danyasz's rat virus also did not succeed in appreciably diminishing the number of rats in places where this agent was tried. From Japan also come reports that give little encouragement for the destruction of rats. In Tokyo alone almost five millions of these animals were killed, and it seemed as though the slaughter had only prepared more favorable conditions for the multiplication of the survivors.

According to Haffkine, the ultimate plan of combating the bubonic plague in the areas in which it becomes endemic consists in conferring on the population immunity from the disease by means of an artificial treatment. As a result of the work in India in the past ten years, Haffkine draws the following conclusions: 1. In a native of India, who is more susceptible to the disease than Africans, Europeans, and some other races, the inoculation now in force reduces the liability to attack to less than one third of what it is in a noninoculated Indian. 2. In the one third of cases which still occur the recovery rate is at least double that in the noninoculated attacked. The ultimate result is a reduction of plague mortality by some eighty-five per cent. 3. In an inoculated European an attack of plague, if it subsequently occurs, has so far always ended in recovery. 4. The inoculation is applicable to persons already infected and incubating plague, and prevents the appearance of symptoms or else mitigates the attack. Some idea of the importance of the control of plague in India may be obtained from the returns for 1907. The total cases of plague from November 24, 1906, to November 9, 1907, were 1,394,947, of which number 1,276,576 were fatal.

#### INJURIES AND THE PREVIOUS CONDITION.

For one reason or another there often arises the question of the influence of a person's previous state of health upon the disability resulting from an injury. A lecture on the subject was recently given at the Hôtel Dieu by M. Brissaud (*Progrès médical*, April 11th). His special topic was the question of whether or not the possibility of such an influence should be considered in adjudicating suits for damages. He maintains that no hard and fast rule on the point can justly be laid down and be regarded by the courts as inviolable. He protests against the French law which ordains that a pregnancy lasting more than 300 days cannot be admitted, with the consequence that a child born even two hours after the expiration of that fixed time, the date of the last marital coitus being known, has been declared illegitimate. The arbitrary rule is adhered to, he says, in spite of a known case in which a woman was violated, became pregnant, and carried the child for 317 days, although she had never had sexual connection before or after the rape. This matter he brings up in his introduction, to support the contention that the law is unjust when it generalizes without regard to exceptional occurrences.

Proceeding to his proper subject, M. Brissaud cites the case of a girl, twenty years old, employed

by a seamstress, who pricked her left thumb with a needle in the course of her work. A very small superficial abscess formed at the site of the puncture, and M. Kirmisson extracted a fragment of the needle through an incision not more than a third of an inch long. A few days later the girl's left hand became painful, and the fingers were in an attitude of contracture in extension. Almost at the same time a new abscess, quite like the first one, formed in the left forearm, and again a piece of needle was removed. A few weeks afterward, the pain and contracture of the hand persisting, a third abscess appeared in the upper part of the arm, and a third piece of needle was cut out.

It was soon afterward that M. Brissaud saw the girl, and found hyperæsthesia and even slight atrophy (from disuse) of the upper left limb. The young woman protested, with tears in her eyes, that she could no longer work, and was disabled for life, and proceeded to enact a scene of violent despair. Some days later she had an abscess of the left breast, and a fourth piece of needle was extracted. It is added that the four fragments, taken together, exceeded an ordinary needle in length. The girl had purposely stuck herself with needles. Her mother bewailed the young woman's hysterical conduct, saying that she had always been "so reasonable, so sweet, so industrious," etc. And, says M. Brissaud, the mother spoke justly; the first prick, accidental as it was, had roused into activity a latent state of hysteria.

#### SOME POINTS CONCERNING SCARLET FEVER.

In the April number of the *Dublin Journal of Medical Science* there is published the graduation thesis of Dr. G. Allan Crowley. It is entitled *Some Points on the Diagnosis of Scarlet Fever*, but the points given do not all relate particularly, certainly not solely, to diagnosis. What the author says is founded on his personal observation of 1,005 cases; he has, therefore, no lack of clinical data, and his thesis reads like the work of a good observer.

Dr. Crowley follows Caiger's division of cases of scarlet fever—somewhat arbitrary, he admits—into three classes, the simple, the septic, and the toxic. The simple cases are those that usually run a mild course, though they are not free from the liability to dangerous complications. The septic cases are those in which some secondary infection takes place, especially that with *Staphylococcus pyogenes*, and is apt to prove more important than the scarlet fever itself. The third, or toxic, class is made up of those

fulminating cases in which the fatal issue is "the direct result of an overpowering and lethal dose of the scarlet fever toxine *per se*."

Dr. Crowley properly insists upon the diagnostic value of the disproportion between the excessive rapidity of the pulse and the moderate amount of elevation of the temperature in the simple cases, though it is observed only in the early period of the fever. It is common enough, he says, to find the pulse from 140 to 160, while the temperature is only between 101° and 102° F. The discrepancy need not in itself give rise to anxiety, though it is a very important aid to diagnosis. As regards the temperature, he thinks there is a tendency on the part of American and Continental authors to record it too high in cases of average severity. We do not remember that such a difference has been noticed before. If it turns out to be real, it may perhaps be accounted for by some variation in the process of taking the temperature; many of our physicians, it is well known, have been taught to seek by extraordinary precautions to elicit the highest possible degree of heat in the mouth. It is hardly to be supposed that the temperature of scarlet fever patients is lower in Great Britain than elsewhere, or that there are geographical variations of the accuracy of clinical records in so simple a matter as thermometry.

The author gives an interesting account of the process of desquamation, especially of the form known as the "pinhole" desquamation, and his description of the rash is minute and accurate. Soon after the rash has faded, he remarks, the diagnosis may be extremely difficult. In that case the following points are of importance: The peeled condition of the tongue, which has not yet had time to renew its epithelium; the appearance of the fauces, which, if the attack has been at all severe, will still show some degree of injection; roughness and dryness of the skin, which is not infrequently of a dirty yellowish color; the presence of enlarged and injected papillæ on such parts as the legs, the outer side of the thighs, and the posterior surface of the arms; and the existence of enlarged and tender glands at the angles of the jaw.

At the height of the rash, says Dr. Crowley, there is often present around the mouth "a pallor in striking contrast to the cheeks, where the flush attains a marked degree." He adds that "the existence of this circumoral ring bears no special significance." There is, however, in rare instances, a *milk white* pallor about the mouth, which is said to be of deadly import and to occur early in the disease, but this is evidently a different thing from the pallor mentioned by Dr. Crowley.

## A NOVEL SOURCE OF LIGHT FOR OPERATING.

The illumination usually available in a farm house is woefully inadequate when it comes to performing even a minor operation. This fact recently led a physician in Rome, N. Y., to put to a novel use the acetylene headlight from his motor car. The car was run close to the window of the room in which the patient lay, and one of the gas lamps was taken off the carriage and into the operating room, the supply of gas being furnished through a long piece of drainage tube. The result was entirely satisfactory, so we learn from the *Scientific American*, as the improvised light made possible an operation which would have been difficult, if not impossible, to perform in an entirely satisfactory manner without the additional illumination furnished by it.

## Obituary.

JAMES KING CROOK, M. D.,  
of New York.

Dr. Crook died on Thursday, April 16th, aged forty-nine years. He was a graduate of the Medical Department of the University of the City of New York, of the class of 1880. He was known as an excellent clinical observer and as a writer possessed of a clear and attractive style.

## News Items.

**Mount Sinai Hospital, New York.**—The George Blumenthal, Jr., Fellowship in Pathology for the current year has been awarded to Dr. Reuben Ottenberg, of New York.

**Syracuse, N. Y., Academy of Medicine.**—At a meeting held on Tuesday evening, April 21st, Dr. Carl Levy read a paper on the Diagnosis of Gallstones.

**The Frederick Douglass Memorial Hospital of Philadelphia** has contracted for the erection of a new five-story hospital building on the south side of Lombard street, between Sixteenth and Seventeenth streets.

**The Medical Jurisprudence Society of Philadelphia** held a stated meeting on Monday evening, April 20th. Henry Lerman, Esq., delivered an address on The Bar as Seen from the Witness Box.

**Meetings of Canadian Medical Associations.**—The forty-first annual meeting of the Canadian Medical Association will be held in Ottawa on June 9th, 10th, and 11th, and the Ontario Medical Association will hold its twenty-eighth annual meeting in Hamilton on May 26th, 27th, and 28th.

**Physicians of St. Joseph's Hospital Organize.**—The present and former physicians of St. Joseph's Hospital, Philadelphia, met on April 14th and organized the Association of Resident and ex-Resident Physicians of the St. Joseph's Hospital. It starts with a membership of seventy-five.

**Consolidation of Medical Journals.**—Announcement is made of the consolidation of the *Carolina Medical Journal* with the *Charlotte Medical Journal*. The new publication will be under the business and editorial management of the latter journal, and the name, *Carolina Medical Journal*, has been retained for the consolidated journal.

**A New Medical Society in Bessemer, Ala.**—The physicians of Bessemer, Ala., held a meeting on the evening of April 9th, and organized the Bessemer Medical So-

ciety, with the following officers for the first year: President, Dr. Thomas C. Donald; vice president, Dr. E. P. Lacy; secretary, Dr. T. I. Conwell; treasurer, Dr. E. V. Colwell.

**The Rock Island County, Ill., Medical Society** held its annual meeting on April 14th and elected the following officers: President, Dr. T. J. Lamping, of Moline; first vice president, Dr. William H. Ludewig, of Rock Island; second vice president, Dr. M. S. Dondanville, of Moline; secretary, Dr. H. L. Youts, of Moline; treasurer, Dr. A. E. Williams, of Rock Island.

**Springfield, Mass., Academy of Medicine.**—The second annual meeting of this organization was held recently, and officers for the ensuing year were elected as follows: President, Dr. W. A. Smith; first vice president, Dr. John A. Houston, of Northampton; second vice president, Dr. Ralph H. Seelye; secretary, Dr. Joel I. Butler; treasurer, Dr. H. W. Van Allen.

**Medical Society of the County of Cumberland, N. J.**—The annual meeting of this society was held in Bridgeton on Tuesday, April 14th. Professor J. C. Applegate delivered an address on Eclampsia. The officers for the ensuing year are: Dr. J. C. Loper, of Bridgeton, president; Dr. C. W. Wilson, of Vineland, vice president; and Dr. A. J. Mander, of Millville, secretary.

**Buffalo Academy of Medicine.**—A regular meeting of the Section in Pathology was held in Tuesday evening, April 21st. Dr. James A. Gibson presented specimens of variations seen in livers hardened *in situ*, and Dr. F. C. Busch read a paper entitled Transplantation of the Supra-renal Gland. Dr. Edwin A. Bowerman is chairman of the section, and Dr. George A. Sloan is the secretary.

**Saratoga Springs, N. Y., Medical Society.**—At a meeting of this society held on Friday evening, April 17th, the general subject for consideration was irreducible hernia. Dr. M. E. Van Aernem read a paper on Varieties and Symptoms of Irreducible Hernia, and Dr. D. C. Moriarta read a paper on the Treatment of Irreducible Hernia. The discussion was opened by Dr. J. F. Humphrey.

**The Hospital Conference of the City of New York.**—The annual meeting will be held on Thursday, April 30th, at 8:15 p. m., at the New York Academy of Medicine. Mr. Richard H. Townley will read a paper on State Inspection and Municipal Aid, and Dr. S. S. Goldwater will read a paper entitled The Unfinished Business of General Hospitals. Officers will be elected to serve for the ensuing year.

**Scientific Society Meetings in Philadelphia for the Week Ending May 2, 1908.** *Monday, April 27th.* Microscopical and Geological Section, Academy of Natural Sciences; Society of Normal and Pathological Physiology, University of Pennsylvania. *Tuesday, April 28th.* Medical Society; South Branch, Philadelphia County Medical Society. *Friday, May 1st.* American Philadelphia Society; Kensington Branch, Philadelphia County Medical Society.

**Improvements for Hudson Street Hospital.**—Plans have been filed for the remodeling of the New York Hospital's House of Relief, at Hudson and Jay streets, to provide better facilities for the treatment of patients. The projected improvements include making the ambulance room in the basement into an x ray room, with isolation and sterilizing rooms adjoining, and remodeling the matron's room and the laundry into apartments for the accommodation of patients.

**The Medical Society of the Georgetown University** held its annual meeting in Washington, D. C., on Tuesday, April 14th, and elected the following officers: Honorary president, Dr. Warwick Evans; president, Dr. John F. Moran; vice presidents, Dr. Edwin B. Behrend, Dr. Thomas F. Lowe, Dr. Loren B. T. Johnson, Dr. Llewellyn Eliot, and Dr. G. W. Wood; corresponding secretary, Dr. Roy D. Adams; recording secretary, Dr. R. A. Hamilton; treasurer, Dr. Prentiss Willson.

**The New Hampshire Medical Society.**—The first biennial and twenty-sixth annual meeting of this society will be held in Concord on Thursday and Friday, May 14th and 15th. A good programme has been prepared, and the meeting promises to be one of interest and value. The officers of the society are: President, Dr. John H. Neal, of Portsmouth; vice president, Dr. John M. Gile, of Haverhill; secretary, Dr. D. E. Sullivan, of Concord; treasurer, Dr. D. M. Carrier, of Newbury.

**Rochester, N. Y., Academy of Medicine.**—The regular monthly meeting of the Section in Public Health, which embraces hygiene, climatology, physiology, pathology, bacteriology, and forensic medicine, was held on Wednesday evening, April 22d. Climatology was the general subject for discussion, and Professor Fairchild delivered an illustrated address on the Superior Climate of Rochester.

**Plymouth District, Mass., Medical Society.**—The annual meeting of this society was held in Brockton, Mass., recently. Dr. Gilman Osgood, of Rockland, delivered an address on Hippocrates, the Father of Medicine, and Professor William E. Cheney, of Tufts College, read a paper on the Accessory Sinuses. Officers for the ensuing year were elected as follows: President, Dr. F. J. Ripley, of Brockton; vice president, Dr. C. S. Millet, of Brockton; secretary and treasurer, Dr. Alfred C. Smith, of Brockton.

**Lectures on the Psychoneuroses.**—Dr. Tom A. Williams, who has taken up his residence in Washington, D. C., after having spent two years abroad in the study of nervous diseases, has made arrangements for a course of lectures on the diagnosis and treatment of the psychoneuroses, dealing particularly with the recent researches of the French school in this branch of medicine. In the mornings the lectures will be on anatomopathology, and the afternoons will be devoted to clinical work. The course will begin on May 25th, and the number of lectures will be limited.

**A Joint Meeting for the Discussion of Tuberculosis.**—A meeting of the Ontario County, N. Y., Sanitary Officers' Association, the Medical Society of the County of Seneca, N. Y., and the physicians of Geneva and Ontario County will be held in Geneva on Tuesday, April 28th, at 3 p. m., in conjunction with the tuberculosis exhibit of the State Department of Health. Dr. H. D. Pease, of Albany, and Dr. Lewis Gregory Cole, of New York, will deliver addresses on the subject of tuberculosis, which will be illustrated by lantern slides. All who are interested are invited to attend.

**The Medical Society of the County of New York.**—A stated meeting will be held at the New York Academy of Medicine on Monday evening, April 27th. The scientific session will be devoted to a "symposium" on obstetric prophylaxis, and papers will be read as follows: The Hygiene and Management of Pregnancy, including the Examination of Pregnancy, by Dr. Austin Flint, Jr.; The Prevention of Maternal Dystocia, by Dr. Richard C. Norris, of Philadelphia; The Prevention of Maternal Infection, by Dr. Edwin B. Cragin; The Prevention of Fetal Infection, by Dr. J. Clifton Edgar.

**A Consolidation of Medical Colleges.**—It is announced that the Medical School of Indiana University and the Purdue School of Medicine are to be united in one school which is to be under the control of the Indiana University. The faculty of the new school will be selected with due regard to the members of the present faculties. A two years' course of medicine will be maintained at Bloomington in addition to the complete medical course at the University of Indiana. The final plans and details of the merger have not yet been arranged, but it is said that the change will be made as soon as possible.

**The Mortality of Baltimore.**—According to the report of the health department of Baltimore for the week ending April 11th, there were during the week 235 deaths from all causes, as compared with 227 for the corresponding period in 1907. The annual death rate in 1,000 of population was 20.60; white, 18.77; colored, 30.29. The principal causes of death were: Measles, 2; scarlet fever, 1; diphtheria, 1; membranous croup, 1; grippé, 1; consumption, 41; cancer, 12; apoplexy, 14; organic heart diseases, 12; bronchitis, 7; pneumonia, 26; Bright's disease, 10; suicides, 3; homicides, 2; accidents, 9; all other causes, 25.

**The Section in Laryngology and Rhinology of the New York Academy of Medicine** will meet on Wednesday evening, April 29th. Dr. P. Fridenberg will present a patient with a congenital defect of the anterior faucial pillars, and Dr. S. Oppenheimer will present a patient with congenital atresia of the larynx. Papers will be read as follows: The Treatment of Fractures and Depressed Deformities of the Nose by a New Method, by Dr. William W. Carter; The Drainage Mechanism of the Normal Accessory Sinuses, by Dr. Sidney Yankauer; A Report of Three Cases of Laryngeal Growth Removed by Direct

**Dr. Koch Compliments New York Institutions.**—During his stay in New York Dr. Koch visited the offices of the health department and was enthusiastic in his praise of the antituberculosis work inaugurated in this city by Dr. H. M. Biggs. He said that Berlin was about five years behind New York in the organization of the tuberculosis crusade, and was watching with interest the progress of the work here. Dr. Koch also visited the quarantine station, and was much interested in the organization of that service. He was particularly impressed by the successful campaign which Dr. Doty has waged against mosquitoes in Staten Island.

#### Society Meetings for the Coming Week:

**MONDAY, April 27th.**—Medical Society of the County of New York.

**TUESDAY, April 28th.**—New York Dermatological Society; New York Medical Union; Metropolitan Medical Society of New York City; Buffalo Academy of Medicine (Section in Obstetrics and Gynecology).

**THURSDAY, April 30th.**—Brooklyn Society for Neurology.

**FRIDAY, May 1st.**—New York Academy of Medicine (Section in Surgery); New York Microscopical Society; Gynecological Society, Brooklyn, N. Y.; Manhattan Clinical Society, New York; Practitioners' Society of New York.

**Canadian Antituberculosis Association.**—The eighth annual meeting of the Canadian association for the prevention of tuberculosis was held in Ottawa on March 18th. The report of the secretary showed that a sanatorium for tuberculosis patients had been established in British Columbia; that one would be established in Manitoba this spring, and that plans were being made for the establishment of sanatoria in Alberta and Saskatchewan. Dr. LaBerge, of Montreal, spoke on Some Civic Aspects of the Tuberculosis Problem, and Dr. Bryce, of Ottawa, delivered an address on the Tuberculous Immigrant. Officers were elected for the ensuing year, and Hamilton was chosen as the place for the next meeting.

**The Undergraduate Medical Association of the University of Pennsylvania** is an association of the students of the University modeled on the organization of the American Medical Association for promoting "the growth of practical accomplishments in scientific medicine among the undergraduates, to prepare them for future usefulness in wider spheres of professional activities, and to unify the interests of the various constituent societies." The first annual meeting of the association was held on Wednesday, April 8th. There was a morning session at 10:30, a luncheon at 1:00 an afternoon session at 2:30, after which Dr. S. Weir Mitchell, the orator of the day, delivered an address on the Conduct of the Medical Life, and a dinner in the evening. The entire affair was very successful.

**Michigan State Board of Health.**—The regular quarterly meeting was held in Lansing on April 10th, with the following members present: Dr. Angus McLean, of Detroit, president; Dr. Malcolm Sinclair, of Grand Rapids, vice president; Dr. Frank W. Shumway, secretary; Mr. Charles M. Ranger, of Battle Creek, and Dr. Aaron R. Wheeler, of St. Louis. A resolution was passed authorizing the secretary to have printed in several foreign languages pamphlets containing instructions regarding contagious diseases, to be distributed free of charge among the foreigners who do not understand English. The secretary was also authorized to issue placards for posting in public places regarding the danger of the spitting habit, and the spread and prevention of tuberculosis.

#### Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Department of Health for the following statement of new cases and deaths reported for the two weeks ending April 18, 1908:

	April 11.		April 18.	
	Cases.	Deaths.	Cases.	Deaths.
Tuberculosis pulmonalis . . . . .	579	211	444	180
Diphtheria . . . . .	168	65	436	51
Measles . . . . .	1,880	48	1,640	46
Scarlet fever . . . . .	985	54	1,095	66
Smallpox . . . . .	106	2	108	1
Varicella . . . . .	106	1	108	1
Typhoid fever . . . . .	101	4	10	1
Whooping cough . . . . .	12	1	13	1
Cerebrospinal meningitis . . . . .	14	7	7	7
<b>Totals . . . . .</b>	<b>4,105</b>	<b>399</b>	<b>3,747</b>	<b>117</b>

## Pith of Current Literature.

1. Chronic Obstruction of the Duodenum by the Root of the Mesentery. By E. A. CODMAN.
2. Acute Yellow Atrophy of the Liver. A Report of Two Cases, One with Ascites. By WILDER TILESTON.
3. On the Significance of Clinical Histories Before and After Operative Demonstration of the Real Lesion. By MAURICE H. RICHARDSON.

1. **Chronic Obstruction of the Duodenum by the Root of the Mesentery.**—Codman, in his paper, wishes to prove his contention that in the human being the transverse portion of the duodenum is more or less compressed by the root of the mesentery. Slight anatomical deviations from the normal or certain pathological conditions may increase this pressure to a varying extent up to the point of complete occlusion of the gut, and when this pressure reaches a degree great enough to give more resistance to the muscular efforts of the duodenum than the closed pylorus, the condition becomes of pathological significance. Thus anatomically the duodenal secretions are brought in contact with mucous membranes unfitted physiologically to withstand their corrosive action. The obstruction favors stasis in the duodenum and thus bacterial invasion of the tissues. He concludes that if these propositions can be proved they will materially alter the present conceptions of the aetiology and treatment of a variety of pathological conditions, e. g., hyperchlorhydria, nervous dyspepsia, duodenal and gastric ulcer, pancreatitis, cholelithiasis, persistent vomiting after laparotomy and in pregnancy, and excessive fluid drainage from wounds in the common duct and duodenum.

10. General Anæsthesia. By ORVAL J. CUNNINGHAM.

1. **Malunion of Bones.**—Beck suggests the following axioms: No bone injury should be treated unless at least one reliable Röntgen ray picture is taken. The Röntgen method, in combination with the usual methods of examination, determines the character of a suspected bone injury. If there is no bone injury the usual treatment consists in massage, followed by temporary immobilization; a movable splint (plaster of Paris) being recommended for the latter purpose. If there is a fissure or fracture, followed by no displacement, manipulation of the in-

jured area must be avoided, and immobilization in the most comfortable position applied. A plaster of Paris dressing answers the purpose best, as it adapts itself to the contours of the body in any shape desired, and it offers no obstacle to the control of the Röntgen rays. After two or three weeks the dressing is removed and massage begun. If a displacement is present, the fracture must be looked on as a most important injury. Reduction must then be tried at once. This may be done under the control of the screen, on a translucent table, a plaster of Paris dressing being applied after reposition is perfect. This is a simple, short, and cheap method, but the impressions on the fluoroscope are by no means so reliable as those made on a plate, and the latter can be studied at leisure. If the facilities allow, a plate should therefore be made before efforts at reduction under the guidance of the fluoroscope are tried. Another method consists in taking two skiagraphs, in different positions, generally in the lateral as well as in the dorsal position. Under the guidance of these plates the reposition is done and a plaster of Paris dressing is applied. A Röntgen picture is taken through it in order to ascertain whether or not reposition is perfect. If it does not seem to be, the dressing must be removed and another attempt at reposition made. If the process of reduction, as frequently happens in displaced fractures, meets with difficulties, anæsthesia should be employed.

2. **Malignant Degeneration of Warts and Moles.**—Babler remarks that the laity should be impressed with the danger of permitting warts and moles to grow, and should be urged to have them excised at once. The early excision of apparently harmless warts and moles will save days of suffering; in many instances the life of the individual will be saved thereby. The moment that warts and moles begin to grow they are almost invariably already malignant growths and should be treated as such.

3. **Static Electricity.**—Snow gives four rules of dosage: 1. The spark gap, when administering the wave current, must not be made so long as to produce too severe pain throughout the inflammatory area, and the gap should be gradually lengthened as it becomes possible; 2, the spark gap should not be so long as to produce spastic or too severe muscular contractions; 3, the static sparks should be regulated in their length according to the depth of the lesion or size of the part under treatment, from one half inch to the fingers, to four inches over the knees and thighs; 4, the convective discharges should not be administered to the extent of local irritation. The author gives a list of diseases in which static electricity should be applied.

5. **Blood Depletion to 296,000 in Pernicious Anæmia, with Recovery.**—Stone reports such a case, from which he draws the following conclusions: The immediate prognosis in certain cases of pernicious anæmia, with blood depletion below 400,000, although serious, is not hopeless. The prognosis depends on the degree of red cell regeneration in the bone marrow, the age of the individual, and the potency of the hæmolytic poison being important factors. Arsenic exerts a rapid specific influence on the degree of red cell regeneration in certain cases

of pernicious anæmia, but whether through direct stimulation to bone marrow activity or through neutralization of the hæmolytic poison, or both, is a point that remains to be settled.

**7. How the Malarial Parasite Perpetuates Its Existence.**—Woldert says that the length of time a mosquito may live in temperate zones has not yet been absolutely determined. In Philadelphia the author kept one living in a glass jar and fed on bananas, from October 28th to December 26th, or sixty days. Some mosquitoes may live in the latitude of Philadelphia during the months of December, January, February, March, and, in fact, throughout the entire year. In Tyler, Texas, he found larvæ of *Anopheles* living on the surface of water of a small pond in midwinter, and after freezing weather. It is undoubtedly true that mosquitoes may live and propagate in regions near the Arctic zone. Rear Admiral George Wallace Melville informed the writer that he had found mosquitoes within 500 miles of the north pole, in latitude 65 to 78 degrees N. Mosquitoes are said to be so numerous in regions near the north pole that animals coming southward during certain months of the year are driven back north again by the swarms of mosquitoes infesting that country. The determination of the length of life of this insect is of special interest in the prevention and prophylaxis not only of malarial fever, but also of yellow fever. Woldert has stained specimens of malarial parasites taken from cases of malarial fever occurring in every month of the year. In every instance but two the specimens were stained by his modification of the Nocht-Romanowski method, and in these exceptions the carbolthionin and Wright methods were used. The types of malarial parasites found in the peripheral blood were as follows: January, tertian merozoites and a few rosettes. February, estivoautumnal ring and signet ring forms. March, tertian rosettes and many rings forms. April, tertian rings and full grown forms. May, half grown tertian forms. June, tertian forms. July, tertian rosettes. August, estivoautumnal rings. September, estivoautumnal rings. October, swollen estivoautumnal rings. November, estivoautumnal rings and full grown forms. December, crescents and estivoautumnal merozoites. Our author has taken the malarial parasite from the peripheral circulation in cases of malarial fever occurring in every month of the year (during winter, when there are presumably no mosquitoes, and also during the spring, summer, and fall, when they are abundant), therefore no one can escape the conclusion that the malarial parasite may live and thrive during the winter months, without the existence of mosquitoes, and that man is its permanent host.

**9. Diagnosis of Tumors and Other Lesions in the Cerebellopontile Angle.**—Weisenburg reports five cases, in two of which a tumor growing from the dura covering the petrous portion of the temporal and the occipital bones gave some of the symptoms of a lesion in the cerebellopontile angle to such an extent that an operation was performed in one. In the third case, there was entire absence of headache, nausea, vomiting, vertigo, and choked disc, and yet sufficient symptoms were present to indicate a lesion in the cerebellopontile angle, to find at operation a cyst, with the consequent, almost total, recovery of

the patient; the report of a case of abscess of the pia which stimulated the symptoms of a tumor in this angle, and, lastly, the report of a case in which a tumor of the fourth ventricle, compressing the inferior vermis, indicated a lesion in the cerebellopontile angle. The cerebellopontile angle is that area between the lateral lobe of the cerebellum and the medulla and pons in which are located the eighth, seventh, sixth, and fifth cranial nerves. Tumors of this area, as a rule, are fibromata, and grow principally from the eighth nerve, less frequently from the fifth and seventh nerves. Such tumors, especially those growing from the eighth and seventh nerves, are favorable for operative removal. Lesions in this area may be classified according to their nature and origin. They may be fibromata, sarcomata, endotheliomata, fibrosarcomata, or they may be cystic. According to the location, they may grow from the eighth, fifth, or seventh cranial nerves; secondly, they may grow from the substance of the cerebellum or pons, and secondarily involve the structures in this angle, and, thirdly, they may grow either from the dura covering the petrous portion of the temporal or the occipital bones, or from both, and secondarily involve the structures in this angle. Inasmuch as tumors of this area, if sufficiently large, must involve the cerebellum, the motor fibres of the pons and the cranial nerves situated there, it is of the utmost importance to recognize the disease as early as possible, and, therefore, the early symptoms are of the greatest importance. These will depend on the situation of the growth. If a tumor grows from the eighth nerve, there will be, at first, diminution of hearing on the same side, with such irritating phenomena as buzzing, rushing, singing noises, etc. Later this will be replaced by total deafness. Very often, however, little attention is paid to the diminution of hearing or the noises in the ear, and the first symptom that the patient will complain of will be that of incoordination as a result of the pressure exerted on the lateral lobe of the cerebellum, or the early symptoms may be those which are the result of increased intracranial pressure, such as headache, nausea, vomiting, vertigo, and choked disc. The symptoms of lesions growing from the dura covering the petrous portion of the temporal and occipital bones and involving the cerebellopontile angle secondarily will be bilateral, the greater involvement being on the side of the tumor. There should be present implication of the cranial nerves on both sides, with difficulty in eating, talking, and swallowing, because of the involvement of the bulbar nerves, incoordination in the limbs, depending on the side of the cerebellum diseased, the general symptoms of brain tumor, and, at times, spastic paresis of the opposite side of the body, because of pressure on the pons, all of these coming on gradually.

#### MEDICAL RECORD

April 18, 1908

1. Constructive Surgery After Extensive Gunshot Wound of Abdomen. By W. M. POLK.
2. A Phenomenal Aortic Aneurysm. By W. GILMAN THOMPSON.
3. A Case of Recurrent Jaundice, Death in Third Attack from Carcinoma of Pancreas. By GEORGE L. PLABODY.
4. Bright's Disease and Its Treatment. By OTTO LERCH.

5. Electromechanical and Thermic Removal of Local Stasis, By WILLIAM BENHAM SNOW.
6. Integrity of Stereognostic Function and of all Forms of Sensation in a Case with a Lesion of the Left Parietal Lobe, By ALFRED GORDON.
7. Fractures of the Tip of the Olecranon Process, By FRANK E. PECKHAM.

**1. Constructive Surgery After Extensive Gun-shot Wound of Abdomen.**—Polk reports the history of a patient who was badly injured by the discharge of both barrels of a shotgun, the muzzle being directly against the body, with three layers of clothing intervening. The contents of the two barrels struck the abdomen at and above the anterior superior spinous process of the left ilium and came out at and above the iliosacral joint, tearing away all the soft tissue from the crest of the ilium and the crest itself, above a line drawn from a point one inch back of the anterior superior process, around the outside of the bone to the upper limit of the sacroiliac joint. The joint was not entered, but the outer half of the transverse processes of the two lower vertebrae were torn off. Many pieces of detached and semidetached bone were scattered throughout the entire field of the deeper parts of the wound. The only portion of the crest that escaped fracture was that in the immediate region of the anterior superior process, but between it and the inferior process this space was stripped of all tissue but the periosteum. Four operations became necessary. The last one is described thus: The first step was the separation of the intestine from the surrounding wall and then closing it. After being separated, the opening in the gut was spontaneously lessened somewhat, but still the large oval opening, narrowing at its extremities and widening at the middle, involved so much of the circumference of the gut, particularly at its widest part, as to raise a doubt as to the proper line of procedure. This doubt was still further increased by the necessity for removing the thickened cicatricized edges in case it should be decided to close this opening, rather than resect. There was ample room for resection had it not been for the attachment at the point of anastomosis. This reduced somewhat the amount of intestine below the traumatic opening at disposal for such an operation. It was concluded to close this opening. Closing it longitudinally would have been unwise, as the gut would have been too much narrowed at the central portions of the opening. It was therefore closed transversely, making thus an elbow in the gut, widening it at that point. Through and through primary sutures were used with the usual peritoneal surface sutures all interrupted. The next question was to provide adequate covering. Fortunately the omentum was abundant and its displacement to the left dependent upon the anastomosis made it easy to draw it over the entire opening. This had expanded after the intestine had been cut out, so that its measurement was now increased from one half to three quarters of an inch, the general outline remaining oval as before. The first step was to provide a parietal peritoneal covering for the restored sigmoid; to this end the omentum was drawn over the intestine without tension, and stitched to the under edge of the abdominal opening throughout its entire circumference. This afforded ample parietal peritoneal covering. It was

out of the question to find either fascia or muscle for the purpose, so Dr. Polk was compelled to rest satisfied with a supercovering of fat and skin. Vertical incisions were therefore made through the skin and fat at either extremity of the opening, the longest arm being through the gluteal region, the skin with the fat was then dissected from its under attachment beginning at edges of wound, and drawn together over the omentum. The major portion of the flap was taken from the gluteal region. A small piece of rubber tissue drain was inserted at the anterior angle of the wound and dressings applied. The patient was then returned to bed. Care was taken by the frequent passage of the rectal tube to keep down the accumulation of gas in the lower bowel. A thorough and through movement was obtained by a mild catharsis on the second day, and from that time on the progress of the case was uneventful. The patient recovered entirely.

**4. Bright's Disease and Its Treatment.**—Lerch states that if Bright's disease is recognized early and proper treatment undertaken, it is curable. Early symptoms, no matter how light, must be regarded as serious. If the favorable time is allowed to pass, cure becomes more and more impossible, relief of distressing symptoms more and more difficult, and the fatal issue is only a question of time. Statistics are unreliable, because the patients are usually carried off by intercurrent diseases; damaged kidneys provide a favorable soil for almost any disease, and death follows, when with these organs sound the patient would pass smoothly through the attack. The treatment of acute nephritis is first of all preventive. During an infectious disease and after the disease has run its course, the kidneys have to be watched and the urine has to be frequently examined. Pure water, vichy, milk, and buttermilk must be freely administered to flush the kidneys, and drugs that irritate them should be given with the greatest caution. Absolute rest in bed is the treatment after the disease has been established, no matter how mild the case. There is no drug known that exercises a beneficial influence upon the process. Thorough elimination by skin, bowels, lungs, and kidney, and rest to the organ are the indications. A flushing of the kidneys, freeing tubules and glomeruli from debris, is desirable. However, the oedema present and the state of the circulatory apparatus must guide the administration of the liquids. The tepid bath increases diuresis and effects a flushing of the kidneys. The bowels have to be kept freely open, sodium and zinc sulphocarbonate given; if diarrhoea is present betanaphthol or other antiseptics may be administered to prevent fermentation. For practical purposes it is sufficient to administer these antiseptics in doses large enough to make the stools odorless or to add bismuth and to continue to increase until salt is found white in the dejections. If the nephritis is due to chilling of surface, the treatment ought to be commenced with a steam or hot air bath. Severe pain in the region of the kidneys demands hot fomentation or a Priesnitz bandage. If oedema is excessive and does not yield to the hygienic and dietetic treatment, the usual measures have to be taken—saline laxatives to produce watery stools—hot baths, hot packs, and hot air baths. Of the diuretics only those that are not

irritating ought to be administered: the tartrates and acetates of sodium and potassium, lemon juice, infusion of juniper berries, infusion of digitalis, and benzoate of sodium. During an acute attack all food must be withdrawn. Chloroform inhalations and hypodermatic injections of morphine to stop spasm; venesection in suitable cases, and hot injections of normal salt solution may be tried—pilocarpine if the lungs are not seriously damaged. The treatment of the chronic form does not materially differ, though rest and diet must be modified to conform to less vigorous demands.

## BRITISH MEDICAL JOURNAL.

April 4, 1908.

with Tracings, and One Post Mortem Examination  
of the Heart, By E. O. JELLINEK and C. M. COOPER.
4. A Specific Treatment of Leprosy,  
By Professor DEYCKE.
5. Electrolysis in Tic Douloureux and in Spinal Sclerosis,  
By D. TURNER.

2. **Cardiac Disease.**—Hurry states that the term "vicious circle" in medical nomenclature indicates a morbid condition in which cause and effect act reciprocally on each other. Such vicious circles are numerous and play an important part in the processes of disease. Vicious circles associated with disorders of the heart may be grouped as follows: (a) Associated with the myocardium. (b) With the endocardium. (c) With the pericardium. (d) With neuroses. (e) With a fall in blood pressure. All these vicious circles can be analyzed into two or more factors which act and react on each other to the progressive injury of the patient, and their recognition is essential to rational treatment. Special points as regards treatment are as follows: 1. The exciting cause must be sought. This may be obvious, e. g., rheumatic fever, or pneumonia and heart failure. But close investigation of detail may be required; thus an ill ventilated, gas lit office or overindulgence in tobacco may so depress the heart, even when organically sound, that the pulse becomes feeble and intermittent and life miserable and useless, the heart and general health depressing each other. 2. It is frequently desirable to actively treat each of the several factors concerned. In pneumonia the heart must be watched as carefully as the lungs. The unsound heart of the laborer must not be stimulated with digitalis and strychnia if no steps are to be taken to lessen the hard work that is preventing compensation. 3. Where there is a choice of treatment, the physician must attack what appears to him the point of least resistance. Hence results a varying *modus operandi* for the same disorder—a variety which puzzles the patient. 4. The close dependence of the heart on the central nervous system is shown by the existence of several vicious circles in nervous introspective patients. There is often a baseless fear of sudden death, which a few well chosen words from a trusted adviser may entirely dissipate. 5. Many vicious circles associated with the myocardium arise from the failure of compensatory changes—e. g., when a mitral regurgitation

is followed by undue dilatation, caused either by degeneration of the myocardium or by the excessive work thrown on the heart. Here treatment may do much to increase the vigor of the myocardium or to lighten its load. By one or both courses the failing compensation may be so restored as to render the heart once more equal to its task. Above all, an ample supply of pure blood must be secured to the myocardium.

3. **Heart Block.**—Jellinek and Cooper report six cases of heart block, with the results of the post mortem examination in one case. Three of the patients were comparatively young, twenty-seven, thirty, and thirty-one years respectively, and two of these died, the third being in the preparoxysmal stage and recovering. All of the patients came under observation complaining of attacks of the nature of semifaints, the patients not quite losing consciousness. Several of the patients complained of auræ or pre seizure sensations. These may be due to: 1. Extra systoles which, coincidently in some cases, in others perhaps regularly, precede the seizure, the description given being not unlike the so called "auræ" in Adams-Stokes's disease. 2. Slight, short seizures, preceding more prolonged ones. 3. The pumping in of blood into comparatively empty bloodvessels after an extra systole has failed to open the aortic valves; this, for instance, causing an additional pulsation in some of the vessels. The attacks seem to occur in spells and are an indication of the temporary breaking down of the ventricular compensation. It is remarkable from what seizures or series of seizures people can recover and afterwards lead a useful life for years. Pulsation of the veins of the neck can only be detected during the shorter, milder attacks. The sounds as heard over the auricles are shortened miniature toneless imitations of the normal first and second sounds as heard at the apex. In no case was there any œdema. Clinically the hearts of four of the six patients were greatly dilated and hypertrophied. Rest in bed was the most salutary factor in treatment, drugs having but little or no influence.

4. **Leprosy.**—Deycke in his studies of leprosy has not succeeded in cultivating the lepra bacillus as seen in the leprous tissue. But he has isolated, however, from several severe cases of nodular leprosy a characteristic microorganism which he terms the *Streptothrix leproides*. The material from which the cultures were made was obtained by throwing back a flap of skin, including a nonulcerated recent leproma, and taking fragments of lepra tissue from the under surface of the leproma, every precaution against outside infection being of course taken. The tissue so obtained was placed in normal salt solution and incubated for several weeks, when the filaments of the streptothrix could be observed growing from the mass in great profusion. Injection of a small quantity of a living culture into a severe case of leprosy at weekly intervals was followed by disappearance of the fever and rapid retrogression of the leprous symptoms, so that at the end of two months recovery was apparently complete. Investigation of the cultures showed that the active principle was contained among the fatty substances. This substance, called "mannin," was found to be a genuine neutral fat, the glycerin ester of a high molecular fatty acid. When smitten down, the bacteria are

given hypodermatically, there ensue more or less intense reactive processes in the leprous tissue, consisting in inflammatory swelling and saturation, pulplike softening, true suppuration, and necrosis of the leprous formations, the normal tissue remaining unaffected. It was found that by combining nastin and benzoylchloride the former was activated to a great extent. The nastin is carried to the lepra bacilli, to which, owing to its near chemical and physical relation, it attaches itself, and then the benzoyl can fully display its well known antibacterial action in removing the fat of the lepra bacilli. And when deprived of fat the lepra bacilli seem to be doomed. The human organism then effects with comparative ease the further dissolution and ultimately the complete destruction of the bacteria nuclei. The writer sums up his conclusions in one short sentence: Benzoyl nastin is an agent which acts directly on lepra bacilli.

7. Motoring Notes, By C. T. W. HIRSCH.

2. **Cancer of the Cæcum.**—Symonds in the third of his Lettsomian lectures on the above named subject points out the characters of early cancer of the cæcum, and shows the comparative safety of operation in suitable cases and the degree of immunity from recurrence that may be secured. The two main signs are the presence of a tumor and the occurrence of early intestinal colic due to obstruction of the ileocæcal orifice. The tumor in its most typical form is unlike any other morbid condition about the cæcum. It is movable, hard, and well defined, and so close to the abdominal wall that it may be grasped by the hand and even lifted from the posterior wall. It may be moved downward and upward for quite a distance, during which movement a gurgle is often felt from air passing through the stricture. The discovery of the tumor by the patient may be the first sign of disease. Intestinal colic is a common initial symptom, and if the patient be taking food at the time of the colic part of the food may be rejected without nausea, and he may return to his meal. Colic may be entirely absent where the disease begins in the posterior wall or just above the orifice. Swellings in the region of the cæcum giving rise to questions of diagnosis may be classified as follows: 1. The conditions resulting from appendicitis. 2. Cancer of the posterior wall with early perforation, fixation, and suppuration. Here the resemblance to subacute cases of appendicitis is very close. 3. Glands in the angle between the ileum and cæcum. 4. Tuberculosis of the cæcum. This occurs in earlier life and fixation arises sooner than in cancer. 5. Actinomycosis in

its early stages resembles more closely that form of appendicular swelling due to a calcareous covered concretion, in that the tumor is fixed and does not disappear. In the later stages, when infiltration and suppuration occur, there is a resemblance to cancer beginning in the posterior wall. So mobile is the tumor in cases of cancer of the cæcum, that until the abdomen is opened one cannot be certain whether extirpation is possible or not. The presence of ascites and of secondary deposits in the peritonæum or liver puts excision out of the question, as does also adhesion to the posterior wall with infiltration of the muscle or with a sinus. Infiltration of the anterior abdominal wall, unless very limited, also renders complete eradication impossible. Where the disease is too expensive for removal, short circuiting will sometimes relieve the symptoms. The writer makes use of the Murphy button in almost all his cases, but supplements it by a row of Lembert's stitches all round.

3. **Delayed Chloroform Poisoning.**—Hunter holds that to connect the symptom complex of post-anæsthetic poisoning exclusively with disturbances in fat metabolism is to exaggerate the importance of this change and to underestimate the importance of the other functional liver disturbances with which disturbance in fat metabolism is associated. The acidosis accompanying increased fat metabolism becomes of grave pathogenetic significance when combined with diminished proteolytic activity, owing to inanition, deprivation of food, or recurrent vomiting. As the result of the diminished absorption of ammonia in the portal blood caused by such conditions the intracellular alkalinity of the liver cell is already at a low level. There then results first of all a serious interference with the proteolytic, antitoxic, and glycogenic functions of the liver (of which the post-anæsthetic nausea is a symptom), and the transference of fat to the liver in increased quantity from its depots is a result. The acidosis which accompanies this increased fat metabolism depresses still further the intracellular alkalinity and proteolytic and antitoxic powers to the point when they are almost in abeyance. There then ensue the characteristic severe toxic cerebral symptoms of the condition which rapidly prove fatal. So that the disturbances in fat metabolism, evidenced by the fat changes after death, and the acetoneuria and acidosis during life, are thus the results rather than the causes of the preceding disturbances in the other functions of the liver. The vomiting which occurs after the administration of anæsthetics is not of nervous origin, but is essentially toxæmic, due to the profound depression of liver function, with consequent diminution in its antitoxic function during the period of the administration. This depression will be the greater if a liver already weakened by disease or by poor nutrition be further unduly weakened by food having been withheld for many hours before the administration. This enforced abstinence from food before administration of an anæsthetic may thus, in individual cases, be carried too far, and it is largely responsible for the fatal effects of delayed chloroform poisoning in exceptional cases. Such effects could, in all probability, be completely prevented if, instead of withholding food, particular care was taken that the patient had always a very nutritious and easily

digestible meal, well sweetened, two or three hours before the operation.

**4. Bacteriology of Scarlet Fever.**—Kerr has made a bacteriological investigation of the throats of 160 patients suffering from scarlet fever, and found streptococci present in 84 per cent. But cultures from forty healthy throats showed streptococci in 83 per cent. Streptococci in pure culture were found frequently in the adenitis and mastoid infections, showing that they play an important ætiological part in the complications of scarlet fever. All the streptococci found were subjected to the well known Gordon tests, but no light was thrown on the ætiology of the disease, as at least seven different strains were found. That the infecting agent is present in the pharyngeal and faucial mucus is absolutely all that has been established for certain regarding the causation and source of the disease. If none of the streptococci in the throat are causative of the primary condition, some other agent must have made it possible for them to obtain entrance to the tissues in order to produce the secondary complications.

7. Homes for Lupus Patients and the Subjugation of the Disease. By ALBERT NEISSER and E. MEIROWSKY.
8. What Should the Physician Do for Tumors of the Bladder? By POSNER.

**1. Surgery of the Lower Segment of the Œsophagus.**—Hildebrand considers operative measures to remove carcinoma of the lower portion of the œsophagus to be hopeless.

**2. Surgery of the Brain and Spinal Cord.**—Küttner reports thirteen cases in this portion of his paper. They are divided into congenital malformations, injuries, and inflammatory diseases. The cases of congenital malformation were one of cephalocele occipitalis inferior cured by operation, one of spina bifida of the upper dorsal vertebra in which death resulted from compression of the medulla oblongata by a sarcoma of the plexus chorioideus of the fourth ventricle, one of spina bifida occulta with defect of the lower segment of the sacrum and of the coccyx, and one of spina bifida occulta of the sacrum with the formation of a tumor. The cases of injury were one of late hemorrhage in fracture of the base of the skull, one of fracture of three cervical vertebrae with pure motor paralysis of both arms by intramedullary hemorrhage followed by perfect recovery, one of fracture of the spinous process of the fourth lumbar vertebra by muscular violence, and one of trophæneutonic gangrene of the foot after fracture of the spine. The cases of inflammatory disease are divided into two parts: 1. Brain abscess and purulent meningitis; one of acute abscess of the brain after

complicated fracture of the skull with recovery after operation, one of acute traumatic abscess of the brain with an enormous prolapse of the brain that recovered with a certain amount of spastic paresis, one of chronic abscess of the left frontal lobe of the brain which simulated a tumor of the cerebellum on the left side, and one of purulent meningitis with the formation of gas. 2. Myelitic processes. Only one case is reported which was of congenital symmetrical paralysis and deformity, due perhaps to a foetal poliomyelitis.

**4. Gastric Disturbance in Masturbators.**—Hirsch reports a case of nervous dyspepsia met with in a man, twenty years old, which was cured by the stoppage of the habit of masturbation.

**5. Decrease of Mortality from Tuberculosis.** Fränkel states that in Prussia there died from tuberculosis 88,283 persons in 1886, 64,450 in 1906. In terms of proportion in 1886, 31.14 to the 10,000; in 1906, 17.26 to the 10,000. The steady decrease in mortality from this disease during these twenty years is excellently shown by a table prepared by the author.

**7. Homes for Lupus Patients.**—Neisser and Meirowsky urge the establishment of institutions in which patients with lupus may be cared for, and think that by this means the disease may become stamped out.

12. The Reaction of the Phagocytes of Elements of Blood on the Bacilli of Tuberculosis. By S. G. DIXON.

**1. The Hygiene of Medical Cases, Particularly in Hospital Wards.**—Edsell believes that infection is communicated in hospital wards much more frequently than is usually suspected, and in medical more frequently than in surgical wards. The ordinary regulations are inadequate in two ways: (1) they consider only a few of the infections, (2) they cover only a portion of the means of conveyance. Isolation of cases is a very incomplete solution, for it can be applied to very few diseases. Infection of the food, and especially of the

milk, when the milk is not pasteurized, is a matter requiring serious attention. The milk when received at the ward should be under the care of a particular nurse and protected from infection. The rest of the food within the ward must also be protected from infection. The nurses and doctors may transmit disease from one patient to another. The patient's mouth must be kept free from infection, hence it should frequently be swabbed out with cotton and a suitable solution. Ward utensils must be frequently boiled, and orderlies must be eliminated from the care of patients as much as possible. Both nurses and patients should be protected from infecting themselves or others.

**2. The Nature and Management of Diabetes Mellitus.**—Osborne states that this term should be restricted to cases in which the sugar in the urine cannot be removed by any dietetic or medicinal treatment. Clinically recurrent glycosuria is, however, frequently a forerunner of diabetes mellitus. Temporary diabetes may be produced by phosphoric, lactic, and hydrochloric acids, by strychnine, arsenic, phosphorus, and carbonic oxide. Glycosuria resulting from irritation of the floor of the fourth ventricle or of the medulla oblongata is well known. Disease of the islands of Langerhans in the pancreas is present in many cases of diabetes. The diabetic eats an excess of proteid and fat in order to get the proper amount of energy from his carbohydrates. His dry skin is due to the great loss of water from the tissues, and he shows predisposition to infections. Diabetic coma is preceded by headache, nervous irritability, and an acid condition of the blood. In treatment of this condition starches must not be too rapidly withdrawn. The diet must be suited to the individual case; medicine is of secondary importance. A warm climate, especially an equable climate, is to be preferred, with freedom from worry, and work that is not fatiguing. The pancreas and suprarenal extracts are the only organic substances which the writer has found serviceable.

**3. The Importance of Early Detection of Aneurysm of the Aorta.**—Arnold states that in examining for this condition one should carefully percuss the area of dullness of the great vessels, note the conduction of the heart sounds in this area, examine both radial pulses simultaneously, examine for the tracheal tug, note all evidences obtained by inspection or palpation, note carefully all the anatomical relations of the aorta, and ever keep in mind the possibility of aneurysm. The early symptoms are usually pain or disturbance with the respiratory apparatus, the latter from pressure on the air passages or the recurrent laryngeal nerve. The symptoms often simulate those of heart disease. There are no pathognomonic signs; the features may be entirely different in successive cases. An x ray examination is useful for confirmatory evidence, for distinguishing from solid tumor, and for detecting aneurysms not discoverable by ordinary methods of examination. While the disease cannot be cured, it can be relieved. It demands limitation of exertion and mental quietude. The vasodilators are the most useful drugs which can be given.

**6. Cholecystectomy.**—Deaver sounds a note of warning against too frequent extirpation of the

gallbladder. The organ serves a useful purpose, and should be retained unless hopelessly diseased. From the standpoint of pathology it is most useful as an avenue for drainage in septic conditions of the liver and biliary passages. If chronic pancreatitis follows removal of the gallbladder, prolonged drainage will be necessary. In such cases cholecystoenterostomy is the procedure of choice. If the gallbladder is removed in the presence of infection of the bile passages, drainage of the stump of the cysticus or of the choledochus with a rubber tube is essential; this is better than draining into the duodenum. In doubtful cases drainage is preferable to removal of the gallbladder, the dangers in the latter operation being always far greater than in the former. Cholecystectomy is always indicated for dropsy, cancer, or other new growth, calcareous degeneration or fibrosis of the gallbladder. If the fundus alone is diseased it should be resected and the remaining portion drained.

**10. The Indican Reaction as Evidence of Enterogenous Intoxication.**—Houghton offers the following working rules: 1. Urinary indican is a product of intestinal putrefaction. There may be putrefaction without the production of indol, but there can be no indicanuria without putrefaction. 2. A maximum excretion of indican, of 100 or more on Frolin's scale, indicates excessive intestinal putrefaction, and the consequent intoxication. 3. A maximum reaction with an index under 100 may be significant, but its interpretation should be guarded by the oxidizing and excretory capacity of the patient. 4. A heavy indican reaction which subsides under treatment indicates intoxication to a lesser degree, but minor variations in the color index have no significance with our present knowledge. 5. No interpretation can be placed upon a negative reaction, as there are too many unsolved factors in the problem.

#### ANNALS OF SURGERY

April, 1908.

1. The Direction of the Jejunum in the Operation of Gastroenterostomy, By B. G. A. MOYNIHAN.
2. Transfusion and Arterial Anastomosis, By R. OTTENBERG.
3. On the Thymus Gland Treatment of Cancer, By F. GWYER.
4. The Parathyroid Glands, By N. P. GEIS.
5. Acute Dilatation of the Stomach and Arterioesenteric Ileus, By W. B. LAFFER.
6. The Removal of Gallstones from the Second and Third Portions of the Common Bile Duct, By F. G. CONNELL.
7. The Reduction en Masse of Strangulated and Non-strangulated Hernie, By E. M. CORNER and A. B. HOWITT.
8. Diagnosis of Renal Disease and Sufficiency, By B. A. THOMAS.
9. Multiple and Consecutive Operations on the Kidneys for Calculi, By W. W. BABCOCK.

**2. Transfusion and Arterial Anastomosis.**—Ottenberg suggests the following points in technique: 1. The vessels must be handled gently, never with toothed forceps. The best instrument is a fine bent forceps. 2. The part to be cufted back is cleaned of its connective tissue by pulling the connective tissue sheath over the cut end of the vessel and cutting it off with scissors. On the end of the other segment much connective tissue should be retained. 3. During the operation the vessels must be

kept moist with salt solution. 4. One should expose one half inch of the vessel to be cuffed and a similar length of the vessel which is to be pulled over the cuff. If the vessels have branches they must be tied close to the vessel with fine silk. 5. The lumen of the ring for clamping the vessels must be as large as the outer diameter of the unopened vessel which is to be cuffed back. The ring must be placed on the smaller of the two vessels. 6. There must be no tension, as in all plastic operations. 7. The part operated on must be immobilized after operation. 8. Temporary blood stasis is best obtained by Billroth's harelip clamps covered with rubber tubing. 9. If the muscular sheath of the vessel contracts it may be relaxed with hot saline solution, or dilated with a small hæmomatic forceps. 10. Absolute asepsis is necessary.

### 3. Thymus Gland Treatment of Cancer.—

Gwyer makes a second report on this method of treatment. His cases, with one exception, were in an advanced stage and inoperable. The following points were noted: 1. With the exception of two or three patients they showed temporary improvement, less pain, reduction in the growth, prompt improvement in the general condition. 2. Several of the patients have died or will soon die. 3. In many of the fatal cases there was no great loss in weight, no pallor and cachexia, no local increase in the tumor. Some of the cases showed marked improvement in general appearance, with no evidence of metastases. 4. The deaths were attributed to progression of the cancer, to the effects of the thymus treatment, or to the effects of some substance liberated by the ingested thymus which was not eliminated. Probably no deaths were caused directly by the ingested thymus, but its continued use may have caused the development of an antibody of such toxicity, persistency, and quantity as to produce the condition which preceded death. The treatment consisted mainly in the use of the dried gland in the form of a powder, the usual dose being two drachms three times daily.

10. The Use and Abuse of Salt Solution, By E. A. BALLOCH.

### 11. Chloroform versus Ether at Columbia Hospital for Women, By J. ABBE.

#### 1. The Significance of Pain in Pelvic Disease

Novak offers the following suggestions: 1. A careful physical examination is of first importance in the diagnosis of pelvic disease, but interesting in

formation will also be derived from the character and distribution of the pelvic pain. 2. The exact nature of the disease should be determined in a given case, as nearly as possible, and not the advisability or inadvisability of an operation alone. 3. Pain in the pelvic viscera is governed by the same laws which apply to the causation of pain in the other abdominal viscera. 4. Neurasthenia may develop from neglected pelvic disease, with diffusion of pain and characteristic symptoms in other parts of the body. 5. Persistent neurasthenia following pelvic operations is frequently responsible for the continuance of unpleasant symptoms. 6. Hysteria with pelvic symptoms has the same characteristics as when associated with other diseases. 7. The removal of normal ovaries for pelvic pain is now regarded as unjustifiable. 8. Fibrocystic ovaries are often found in women who are in perfect health. Operation on such organs should be conservative. 9. Pain is the resultant of a lesion and a patient and in order to understand its significance both these factors must be carefully studied.

#### 10. The Use and Abuse of Salt Solution.—

Balloch reaches the following conclusions: 1. Physiological salt solution is a fluid which is isotonic with the plasma of the blood. 2. Its field of therapeutic usefulness is in conditions which cause alterations in the quantity or quality of the plasma. 3. The quantitative alterations are chiefly those which are caused by hæmorrhage and obstruction of the upper bowel. The qualitative alterations are caused by the various toxæmias. 4. The exact percentage of salt in the solution is important, and extemporaneous solutions are to be condemned, owing to the danger of hæmolysis. 5. The subcutaneous tissue forms the most useful avenue for the introduction of the fluid. The intravenous route may be used in emergencies, and for postoperative purposes the rectum is most serviceable. 6. Its use for irrigating purposes in abdominal surgery will not prevent the formation of adhesions, and it is probable that its use for washing away pus blood and debris is no more effective than dry sponging.

#### 11. Chloroform versus Ether at Columbia

Hospital for Women.—Abbe thinks advances in general and local anæsthesia in the past few years have been as great as in any branch of medicine. Local anæsthesia now suffices for many minor and major operations, a weak solution of cocaine, with one or more adjuvants, being entirely efficient. Spinal anæsthesia has undergone improvements and is satisfactory for operations on the legs and lower portion of the abdomen. General anæsthesia, following hypodermatic injection of morphine and hyoscine, requires very little of the inhalation anæsthetic. In some conditions, especially in obstetrics, the hypodermatic injection takes the place of the inhalation anæsthetic. New drugs have been proposed for inhalation anæsthesia. Ether and chloroform are still supreme, however, notwithstanding their disadvantages. The features to be eliminated in anæsthesia are: (1) The disagreeable features of administration. (2) Irritation of the mucous membrane of the air passages and the dangers of inhibiting the reflexes of respiration and of cardiac action during the anæsthesia. (3) Postanæsthetic poisoning as shown by nausea, vomiting, suppression of urine, nephritis, acidosis, and pneumonia.

## Proceedings of Societies.

### MEDICAL SOCIETY OF THE STATE OF NEW YORK.

*One Hundred and Second Annual Meeting, Held in  
Albany, January 27, 28, 29, and 30, 1908.*

The President, Dr. FREDERIC C. CURTIS, of Albany, in the  
Chair.

(Concluded from page 714.)

**The Mosquito: Its Relation to Disease and Its Extermination,** was the title of a paper by Dr. A. H. DOTY. In addition to malaria and yellow fever, he said, the mosquito was also charged with the dissemination of elephantiasis, and to some extent bubonic plague, and still all the habits and history of this pest were but incompletely known. It had been shown that they breed only in water, and this they must have present for at least two weeks, usually not in large bodies of water, but in small, stagnant pools, tin cans, broken crockery, etc. The mosquito did not wander far from its breeding place, and one was capable of producing from one hundred to two hundred eggs at a time. The larvæ were commonly known as "wigglers," and they had to rise at intervals to the surface of the water in order to obtain air. After about ten days they became larger, particularly the head, and in a few days more burst their envelope and became winged mosquitoes.

He believed petroleum to be the most effective means of extermination, as it suffocated the larvæ by forming a film upon the water, which the air tube could not penetrate. A pint of oil was advised for every twenty-five square feet, and the application was to be repeated every ten days or two weeks. Bichloride of mercury, carbolic acid, and other such agents were often used, but were pronounced dangerous to both men and animals, and uncertain as to result.

**The Relationship Between Bovine and Human Tuberculosis.**—In this paper Dr. STOWELL stated that there were 120,000 deaths annually from tuberculosis; that sixteen per cent. of all cattle tested suffered from it, and that cows were thought to be one of the chief sources of the disease. All animals, and especially young children, were susceptible to it, and it might enter through an abrasion, through the respiratory passages, or through the intestinal tract.

He referred to a children's hospital which was supplied with milk in part from the average New York City milk and in part from a particular herd of thirty cows, which were afterward found to be suffering from tuberculosis. In the wards which had been supplied by the farm milk there had developed no more cases of tuberculosis than in those supplied by the ordinary city milk, and so he concluded that tuberculosis was not so frequently transmitted by milk as was ordinarily supposed.

**Oxygen in Surgery.**—In this paper Dr. WILLIAM S. BAINBRIDGE said he believed that the profession had long overlooked the medical properties of this valuable agent, and he hoped to stimulate investigation and place it upon its proper basis. In surgery oxygen had its most promising field, and

he recommended its use in wounds and injecting it into the abdominal and pleural cavities, joints, etc. It should first be warmed to 85° or 90° F. and passed through a tube into the cavities mentioned. In the pleural operation the tube should be attached to the end of an aspirating needle. It stimulated the pulse and respiration and gave to the blood a better color.

He cited seventeen cases of infection, most of them peritoneal, in all of which there had been marked improvement after its use. He believed the possible fields of usefulness for oxygen to be as a stimulant to muscular contractions in intestinal paresis; after all laparotomy operations, especially with pus; to lessen pain; as a general stimulant; as a means of lessening shock after the perforation of typhoid fever; to reduce to a minimum the danger of acute dilatation of the stomach; to be of value in shock, asphyxia, hæmorrhage, ascites, and peritonitis.

Dr. GOTHMAY stated that this plan of treatment certainly did straighten out the pulse, relieve nausea and vomiting, and stimulate the patient generally. A few days ago he tried to kill an animal by over-distending the abdomen, but the pulse and respiration remained in an even line and not depressed. The animal came out of an anæsthesia of two hours and fifteen minutes in five minutes. Thus he concluded that there was no danger from overdistention.

Dr. BAINBRIDGE said that in his talk he did not mention the thoracic cavity, but that he had used it in bleeding from the lung to compress and collapse that organ, but he observed that the oxygen was absorbed almost too quickly to act as an efficient lung compressor.

**The Significance of Uterine Bleeding.**—In this paper Dr. JOHN A. SAMPSON asserted that the modern improved results in diphtheria and many other conditions were due for the most part to more accurate diagnoses. In no department of medicine was an early diagnosis so essential as in gynecology. Uterine bleeding was often a symptom of malignancy, polypi, abortion, and many other conditions, and the purpose of the paper was to show how these various conditions might be recognized.

An early diagnosis saved the patient from the symptoms resulting from the bleeding, such as anæmia. In ectopic gestation the mucosa of the uterus underwent the same changes as occurred in normal pregnancy, and a decidua was formed. At the sixth, eighth, or tenth week bleeding might occur, and pieces of decidua were often found in the discharge. From a lacerated cervix slight and inconstant hæmorrhage might occur, especially upon straining or during the congested state of pregnancy.

He referred to the frequent association of retroflexed uterus and an hypertrophied condition of its mucosa. Under such conditions the menses would be prolonged, profuse, and possibly painful. The type there was seen to be a menorrhagia, characterized by slight bleeding in the intervals.

A polyp was defined as a localized hypertrophy of the mucous membrane, which caused symptoms quite similar to those of the previous condition. When they formed in the cervical canal they were

seen to extend down into the vagina and bleed upon straining, even in the interval. A subserous myoma did not cause any hæmorrhagic disturbances.

Inasmuch as cervical cancers were easily injured, bleeding often occurred early. If it was of the inverted type, an ulcer was the common result, and this was very prone to hæmorrhage. On the other hand, bleeding might be slight and inconstant, and not observed till late in the disease. This last type of cancer was seen to be much more malignant, and when profuse bleeding did occur it was apt to indicate metastasis.

**Acute Flexures, Angulations, of the Sigmoid and Colon** was the title of a paper by Dr. J. P. TUTTLE (see page 479).

**Aerotherapy in Certain Toxæmias of Childhood.**—Dr. F. W. LOUGHRAN, in this paper, quoted many textbooks on the treatment of different conditions, all of which seemed to consider an even temperature of from 60° to 70° F. indispensable. The open air treatment had long been recognized as a cure, especially in chronic diseases. He did not believe this fresh air a "cure all," and thought that drugs were often necessary in conjunction.

**Vascular Crises.**—In this paper Dr. H. L. ELSNER stated that arteriosclerosis might exist for years and give rise to no symptoms whatever, or it might cause marked symptoms of an acute nature. These might subside and not return for years. In young subjects he believed the disease to be due to syphilis as a rule. A person apparently normal might suddenly have an attack of angina pectoris, recover, and never suffer a relapse, and arteriosclerosis was usually discovered accidentally, especially in old people.

By the vascular crises referred to he meant the acute symptoms following a sudden spasm or possibly sudden dilatation of the small bloodvessels. The cause of it might be an extra tax upon the organ involved, such as the unusual amount of work required of the heart when a patient took a rapid walk after a hearty meal. The closure of a coronary artery in the heart did not, in his opinion, cause death, but if both were obstructed a fatal result was inevitable. He believed Adams-Stokes disease, or heart block, due to arterial spasm which in some way influenced the nutrition of the bundles of His, and the symptoms were due to a repeated shutting off of nutrition to the heart muscle.

Angina of the heart might in some cases give rise to symptoms below the diaphragm, and abdominal angina and coronary angina might alternate with each other or be associated. A person might be apparently in good health and suddenly be seized with aphasia or even hemiplegia, and in four or five minutes recover slowly. Such a condition, in his opinion, was due to vascular spasm. Such patients were especially predisposed to cerebral hæmorrhage, because spasm of the cerebral vessels was always found to be associated with diseased arteries. Many painful affections of the limbs were seen to be due to vascular spasm. In examinations of patients he advised an investigation of the arteries as well as of the heart itself. The prognosis and treatment were not given as satisfactory, but light, nutritious diet, rest, and vasodilators would give the best result.

**The Causes and Treatment of High Arterial Tension.**—Dr. L. F. BISHOP, in this paper, took up the diagnosis of high arterial tension, and said that for this purpose no instrument could ever replace the fingers, but by this crude method low tension appeared lower than it really was. He described an instrument of his own invention for the determination of blood pressure.

Dr. JACOBÍ said that he considered every one over thirty-five years old more or less a sufferer from arteriosclerosis. It often did not begin uniformly, but in the kidneys, brain, periphery, or heart. When it started in the heart it caused angina. He advised the physician always to examine the urine and kidneys of a man or woman over forty years of age. A slight trace of albumin was said to be normal, but this was not so. Such patients should be examined frequently and kept under observation; they were undoubtedly sufferers from high arterial tension, and arteriosclerosis was seldom seen without Bright's disease. He declared casts and epithelial cells to be evidence of arteriosclerosis. The remissions he believed to be due to a wavering in the nutritive circulation of the nerves, the sudden improvement that took place after an attack to be due to the establishment of a collateral circulation, and the temporary aphasia described in the paper to be due to thrombosis of the minute bloodvessels in that area of the brain. As treatment for this condition, he recommended regular light diet containing but little calcium, hygiene, and alkalies, nitrites and lactates.

**The Diagnosis of Pulmonary Tuberculosis by Tuberculin and Other Methods.**—Dr. L. BROWN, in this paper, stated that all to-day were agreed upon the importance of an early diagnosis in tuberculosis, because only in those cases where an early diagnosis had been made could a favorable reaction to treatment be hoped for.

He believed that the family history had been given too much weight; if positive it was of value, but if negative it was of no weight, and a history of exposure to the disease, of anxiety, overwork, debility, anæmia, or excesses was of greater importance.

He had observed that symptoms often came on before any definite physical signs could be made out, such as a slight but constant rise of temperature, persistent rapid pulse, increased nervousness, some loss of weight and strength, cough, expectoration, dyspnoea, hæmoptysis, and fistula in ano. All these, taken in connection with a history of exposure, were most conclusive. In case of any suspicious the patient should be instructed to bring an early morning specimen of sputum. If the tubercle bacilli were found it denoted ulceration, and the disease was then no longer in its early stage. The opsonic index was not deemed practical. Examination of the feces might be important, especially in patients who would persistently swallow the sputum. The injection of the sputum into guinea pigs was given as a valuable means of diagnosis.

In the physical examination of the patient he should be instructed to breathe out, cough, and breathe in. By this method râles could often be heard at the apices of the lungs. Percussion was not so important as auscultation. Patients concerning whom there was any doubt should be reexamined.

ined at frequent intervals. On the other hand, the absence of physical signs did not conclusively prove the absence of tuberculosis.

As a last resort tuberculin was used when other means had failed. The first dose given was always to be one of sterile salt solution to exclude any nervous reaction. Other diseases had been said to react to tuberculin, but this had yet to be proven.

The diagnosis from bronchitis, malarial disease, nervous dyspepsia, etc., was said to be extremely difficult at times. He emphasized the fact that tuberculosis was a widespread and contagious disease from which our own friends and family were not exempt.

**Œsophagoscopy and Bronchoscopy.**—Dr. HALSTED exhibited a case of instruments for the examination of the upper digestive and respiratory systems. Cocaine or general anesthesia might be used. The object of the paper was to show a means of directly examining the œsophagus, trachea, etc.

**The Emmanuel Church Movement of Boston and the Treatment of Psychoneuroses.**—This paper, by W. C. KRAUSS, was read by title.

**County Laboratories and Their Uses** was the title of a paper by Dr. ORLANDO HALLENBECK. He referred to the inadequate means of information available to practitioners remote from large centres, and believed that if every county had its own bacteriologist and laboratory it would be a profitable investment for the people at large. He asked how many cases of inflamed throat were diagnosed as diphtheria, quarantined, etc, and *vice versa*, and in how many cases of tuberculosis a similar mistake occurred.

He thought, as the people were to derive the benefit, that they should pay the expenses of the institution, when an individual alone would be benefited by any examination of specimens, etc., that he should pay a small fee in return, and that the entire enterprise could be carried out for \$1,500 per annum. He believed that the laboratory should be inspected at regular intervals, and the bacteriologist in charge be required to render reports, and stated that the cost of the building would be about \$1,000 and that of the equipment about \$400.

He asserted that many specimens would be examined that would never be sent to a State laboratory or one at any great distance, and believed that these laboratories should operate with the State Health Department for the good of the general public.

Dr. BUSH said that, following the example set, the county of Chemung had started legislation which would give the board of supervisors power to establish a laboratory and employ a bacteriologist. And he thought that possibly a general bill should be pushed which would give all the counties of the State the same privilege. He asked the sentiment of the meeting in regard to the matter.

Dr. SCHOONMAKER, of Clifton Springs, stated that he had visited the laboratory referred to in the paper, and that it was in every way complete and efficient. He had observed a better and more scientific tone in the general practice of the county.

Dr. JACOB stated that every legislator in the State should have a copy of Dr. Hallenbeck's paper, and he did not believe that any one of them could resist

the suggestions and appeals embodied therein; a resolution should be framed to that effect.

Dr. W. R. TOWNSEND, the secretary, replied that he would frame the desired resolution.

Dr. STRANAHAN stated that in the course of a conversation with Dr. Potter he had been shown a bill that would shortly be introduced which will meet all the requirements of Dr. Bush.

A resolution was framed by Dr. Townsend that a committee be required to see that the paper of Dr. Hallenbeck be printed at an early date and copies sent to each member of the Senate and Assembly of the State of New York, with resolutions endorsing the paper.

Dr. BUSH said that he did not think that the resolution went far enough, that it should endorse a general bill, that the society should take immediate action, and that sentiment should be made in favor of each county possessing its own laboratory. So Dr. Bush moved the amendment, which Dr. Townsend accepted, that the Committee on Legislation be instructed to use its influence for the passage of a law for the establishment of laboratories and the office of bacteriologist all over the State.

The PRESIDENT spoke of two things which had impressed him during the reading of the paper: That it was a pattern for all the counties of the State to follow; that a body of men had convened and done something; that there was nothing that a county society or the State society could fail to accomplish provided it was sane and reasonable.

**What New York Is Doing for Its Crippled Children.**—This paper, by Dr. N. M. SHAFFER, was read by title.

**The Intracranial Complications of Middle Ear Suppuration.**—Dr. S. J. KOPETZKY read a paper in which he stated that the pus might reach the cranial cavity either through natural anatomical channels or by passages formed pathologically by necrosis, and that by extension might affect the jugular vein or the semicircular canals. He believed that complications occurred usually from one to five years, more often in males than in females, between the ages of four and six years. The course of the acute disease was from two to four weeks; of the chronic, from fifteen months to seven years. Any of the fossæ at the base of the skull might be involved, thus giving rise to symptoms referable to each.

Meningitis of extradural origin was one of the most common complications. In cases of abscess, lumbar puncture did not always show the cerebrospinal fluid to be under tension.

**Chronic Middle Ear Deafness.**—In this paper Dr. W. SOHIER BRYANT referred to the importance of the potency of the Eustachian tube and to the difference between middle ear suppuration and middle ear catarrh. He believed all forms of middle ear disease but the congenital were amenable to treatment, and the improvement following treatment in all other cases justified the effort.

**Medical Libraries for Small Centres.**—In this paper Dr. SMITH BAKER said that the scientific reading of the average practitioner was very limited, owing to routinism, arrest of enterprise, or lack of books. The establishment of libraries would be a

source of benefit not only to the profession, but indirectly to the public as well. He believed the present system of every one's buying his own books to be wasteful and inefficient, and instead of each man's buying practically the same books, physicians should assume a fraternal spirit and have a common library which would avoid duplicates and thus have a greater degree of efficiency. He quoted Dr. William Osler as saying: "It would be hard for me to speak of libraries in terms which would not appear exaggerated."

He said that such libraries might be kept in the offices of the physicians interested, each in turn, or when it became too cumbersome, a part of a local city or town library might be devoted to medical books, and the State library at Albany might co-operate with the smaller libraries for the distribution of medical literature.

Dr. A. M. VANDER VEER said that, as he understood the paper, its purposes were threefold—to stimulate among the practitioners of smaller towns and villages the desire to obtain the current medical literature; to establish in connection with local libraries a medical department; and to secure the cooperation of the State library at Albany in the carrying out of these purposes. The library at Albany was now in a position to send out books as a circulating library, and many more volumes, now boxed up, would be available as soon as the new library building, now under construction, was completed.

Dr. JACOBI spoke of the existence of the Association of Medical Librarians, and stated that it could do more and better work with increased membership; that for a number of years the exchanges had been copious, but that they could be more so. He advised physicians in towns that had no library to become members of that association.

**Instruction in Physiology and Hygiene in the Public Schools.**—Dr. GEORGE MILES, in this paper, said he believed that there was much printed matter, and there were many confused ideas upon just what should be taught in the public schools, but that it was better to teach nothing at all than that which was untrue. All physiological teaching seemed to hinge upon the evil effects of alcohol and narcotics upon the body. He believed that temperance and self control should be taught, but also the effects of heredity, exercises, sanitation, etc., and that such education should be honest and sound. Most children got but very little physical instruction at home, so they should get it in school. Oral lessons should be given before the regular lessons, and the teachers themselves should be taught to adapt themselves to this method.

He criticised most school textbooks upon physiology as giving too much space to the bones and muscles and not enough to the special senses, and said that children should be taught the care of the eyes and what wholesome foods were and how to see, hear, feel, talk, eat, and walk properly. What was taught should have higher ends than the mere accumulation of facts; it should give knowledge of how to keep well. He asked of what good were Greek and Latin when the child knew nothing of the laws of his own body, and of what value were science and languages when the health was gone. He advised teachers not to let the evils of alcohol and

narcotics overshadow instruction as to how to live properly, and to instil one point at a time into the minds of the children, so that when they grew up they would be of value to them, and so that in after years they might look back and call their teachers blessed.

**The Nature and Cause of Colic.**—This paper, by Dr. G. F. SCHIELDS, was read by title.

**Closing Remarks by the President.**—Before adjourning the meeting, the PRESIDENT made a few closing remarks. He said that he felt honored in the position which he was about to vacate, because of the illustrious men who had preceded him and also because of his successor, Dr. Trudeau. He believed that the past year had been one of great value to the society in fixing it along better ways than ever before. He referred to his duties as grateful tasks, and wished to thank the various officers and committees for the cheerful and efficient assistance tendered during the past year.

Dr. JACOBI said that while he was chairman of the Committee on Prize Essays for the past few years he had been kept very busy doing nothing, and he urged men capable of writing essays to take up this work. He believed, in fact, knew, that the president was entirely too modest in giving credit to various officers and committees when the greater part of it really belonged to Dr. Curtis himself. He spoke of the long, active, and valuable career of the retiring president in the State society, and called for a vote of thanks to him for his most successful administration.

## Letters to the Editors.

---

### THE HAVERSTRAW COLONY.

319 EAST TWENTY-THIRD STREET, NEW YORK.

April 10, 1908.

*To the Editors.*

The Senate Finance Committee has reported on the bill for the purchase of the Haverstraw Colony site with the appropriation cut nearly in two. The site is a narrow valley protected by steep hills from intrusion on three sides. The commission selected only such plots as were indispensable to secure the strategic control of the valley, the water supply, the clay pits for brick making, and the railroad siding.

With the reduced amount now proposed (\$100,000) the colony will be flanked by a fringe of summer boarding houses, and along the railroad directly in front of the administration group will spring up a row of saloons, hovels, and the usual surroundings of the brick making industry, which even now is trying to acquire the clay pits.

Inmates could not be allowed to work or stay outside of buildings without close surveillance, which means increased cost to the State for attendants and curtailment of the happiness and industrial efficiency of the patients. This is the unfortunate condition now existing at the Newark Asylum, from which, in spite of constant vigilance, several helpless women inmates have been enticed away by intruders, against whom the institution has not even adequate fence protection. At Haverstraw the entire colony is

safely isolated, or may be, if the whole site recommended (costing \$188,575) is purchased.

This argument is entirely aside from the fact that, given ample land for tillage, the institution can raise much of its own supplies, with great benefit to the health of the inmates. There is every reason, both of business economy and of humanity, why the full site should be secured now. It will be next to impossible to get it piecemeal later.

The press all over the State has already cooperated very generously with us in getting the facts before the public. I hesitate to urge you to give further space to a matter of relatively minor public interest, but if we do not speak out for these broken lives, and do it now, it may mean to thousands of them the difference for life between being cooped up in an overcrowded institution and living and working out in the open, under conditions almost as happy and natural as if they were normal citizens. Surely the State can afford the little extra land needed to accomplish the latter result.

HERBERT S. BROWN.

### Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

*The Conquest of Cancer.* A Plan of Campaign, being an Account of the Principles and Practice Hitherto of the Treatment of Malignant Growth by Specific or Cancerotoxic Ferments. By C. W. SALEEBY, M. D., F. R. S. (Edin.). New York: Frederick A. Stokes Company, 1907. Pp. xxiv-361.

It is with some trepidation that one takes up for notice this aggressive volume of Dr. Saleeby's. The writer is so convinced of the importance of his message, he is such a militant advocate, and he is so cocksure of the efficacy of the trypsin treatment that his attitude will hardly admit of questioning without bringing upon his hapless critics a storm of indignant abuse. It is perhaps not without significance that the book has been more favorably received by the newspapers than by the profession and the medical journals. We are convinced that, whatever may be the merits of the trypsin treatment, it will be given a fair trial, and that Dr. Saleeby is unjust in assuming that physicians generally are prejudiced against the use of any measure which promises relief for so frightful a scourge as cancer. He certainly has not a monopoly of unselfish and humane interest in this large subject, and it is difficult for us to understand how a writer who has had a medical education can so far forget the best traditions of his profession as to directly charge surgeons with indifference or hostility to the trypsin treatment from interested motives. Dr. Saleeby is fond of drawing a parallel between the struggle of trypsin for recognition and the reception accorded in the beginning to Christianity, the reforms of Savonarola, and the scientific truths of Giordano Bruno and of Galileo. If this doughty champion is really the herald of an important new truth he will not in this age be either crucified, burned, or imprisoned, but will, we believe, live to see it uni-

versally accepted if it has only half the value he alleges for it. His judicious friends will, however, regret the acrimonious and controversial tone he has adopted in his advocacy of it.

*An Introduction to the Study of the Infant's Stool.* By PAUL SELTER, M. D., Solingen, Germany; Translated by HERBERT M. RICH, B. L., M. D., Detroit, Assistant in Diseases of Children, Detroit College of Medicine. The Detroit Medical Journal Company, Detroit, Mich., 1907.

This pamphlet presents in an easily accessible form a systematic account of the study of the infant's stools. It is a translation of a German monograph which appeared in the beginning of 1905.

The author, Dr. Paul Selter, of Solingen, Germany, intends to demonstrate that we are able to determine some very important facts from the examination of the infant's stool; we can tell whether any food element is properly digested and assimilated, and in many cases we can decide which element is not so disposed of. We then may correct the faulty feeding and thus improve the general condition of the infant.

The booklet is well translated and will certainly appeal to every physician whose practice brings him into contact with infants.

*Kurzes Lehrbuch der organischen Chemie.* Von WILLIAM A. NOYES, Professor der Chemie an der Universität Illinois. Mit Genehmigung des Verfassers ins Deutsche übertragen von WALTER OSTWALD, und mit einer Vorrede von Professor WILHELM OSTWALD. Leipzig: Akademische Verlagsgesellschaft M. B. H., 1907. Pp. xxiv-722.

Professor Noyes's standard textbook on organic chemistry appeared for the first time about five years ago. It was so well received that Professor Ostwald, of the University of Leipsic, proposed to the author a German translation. This version now has been published. The contents of the English original are so well known that we shall not refer to them. The translation leaves nothing to be desired; in fact, the book reads more like an original composition than like a translation. Some changes have been made to adapt it to the use of German students. Of great advantage is a full index.

*A Textbook on Uric Acid and Its Congeners.* With Special Reference to its Physical and Chemical Properties and Accumulation in the Organism. Together with the Disease Processes Arising Therefrom and Their Etiological Therapy. For Medical Students and Practitioners. By GEORGE ABNER GILBERT, M. D., Member of Local, County, and State Medical Societies of Connecticut, etc. First Edition. Danbury, Conn: The Danbury Medical Printing Company, 1907. Pp. 310.

The author has studied with great industry the uric acid question as it appears to him and as it is treated in the medical literature of to-day. He has thus brought together from all available sources the results of the experimental work of American, English, French, German, Russian, and Swedish investigators. He comes to the conclusion that uric acid is one of the waste products of the human organism most frequently retained and responsible for many of the common ills. We should therefore "endeavor to prevent the body from becoming highly charged with uric acid," a dictum of Minowski in *Die Gicht*, who suggests trying to effect this desirable object by decreasing the formation of uric acid, by furthering its excretion, by hastening

the further oxidation, and by increasing the solubility of uric acid in the blood and tissues. This will be best achieved by the alkaline eliminant mode of treatment.

#### BOOKS, PAMPHLETS, ETC., RECEIVED

An Aid to Materia Medica. By Robert H. M. Dabarn, M. D., Professor of Surgery and of Surgical Anatomy, New York Polyclinic Medical School, etc., Fourth Edition, Revised and Enlarged, by Eden V. Delphay, M. D. New York: The Macmillan Company, 1908. Pp. xi-338. (Price, \$1.75.)

Climate Considered Especially in Relation to Man. By Robert DeCourcy Ward, Assistant Professor of Climatology in Harvard University. Illustrated. New York: C. E. Putnam's Sons. London: John Murray, 1908. Pp. xiv-372.

Thirty-first Annual Report of the Board of Health of the State of New Jersey for the Year 1907, and the Annual Report of the Bureau of Vital Statistics. P. 432.

The Submucous Resection of the Nasal Septum. A Detailed Description of the Flap Method. By Otto T. Freer, M. D., Professor of Rhinology and Laryngology, Chicago Polyclinic, etc. With Twenty-four Original Illustrations. Chicago: Journal of Ophthalmology and Otolaryngology, 1908. P. 51. (Price, 50 cents.)

Die Hautkrankheiten. Von Prof. Dr. A. Jarisch. Zweite, vermehrte und unbenutzte Auflage. Mit 7 Abbildungen im Texte. Bearbeitet von Prof. Dr. Rudolf Matzenauer, I. Hälfte (Vorwort, Inhalt und Bogen 1-38). II. Hälfte (Bogen 39-60 und Register). Wien und Leipzig: Alfred Hölder, 1908. Pp. 1110.

### Official News.

#### Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the surgeon general, United States Public Health and Marine Hospital Service, during the week ending April 17, 1908:

Smallpox—United States			
Places.	Date.	Cases.	Deaths.
Alabama—Huntsville, vicinity.....	January-April.....	50	1
California—Los Angeles.....	March 21-28.....	7	1

#### Public Health and Marine Hospital Service:

Official list of changes of stations and duties of commissioned and noncommissioned officers of the United States Public Health and Marine Hospital Service for the seven days ending April 15, 1908.

CARRINGTON, P. M., Surgeon. Granted leave of absence for four days, from April 8, 1908, under paragraph 189, Service Regulations.

COBB, J. O., Surgeon. Relieved from duty at Cairo, Ill., and directed to proceed to Milwaukee, Wis., assuming charge of the service at that port.

GOLDBERGER, JOSEPH, Passed Assistant Surgeon. Granted leave of absence for seven days, from April 9, 1908.

GUITERAS, G. M., Surgeon. Directed to proceed to Pascagoula, Miss., for special temporary duty, upon completion of which to rejoin his station, at Mobile, Ala.

JACKSON, J. M., Acting Assistant Surgeon. Granted leave of absence for ten days, from April 4, 1908.

JAMES, W. F., Acting Assistant Surgeon. Granted leave of absence for thirty days, from July 1, 1908.

McINTOSH, W. P., Surgeon. Directed to proceed to Boston, Mass., for special temporary duty, upon completion of which to rejoin his station, at Portland, Me.

MEAD, F. W., Surgeon. Granted leave of absence for ten days, from April 12, 1908.

NYDEGGER, J. A., Passed Assistant Surgeon. Granted leave of absence for two days, from April 11, 1908, under paragraph 191, Service Regulations.

OAKLEY, J. A., Passed Assistant Surgeon. Granted leave of absence for one month, from April 15, 1908.

RICE, W. E., Acting Assistant Surgeon. Granted leave of absence for fourteen days, from May 1, 1908.

SCHERESCHESKY, J. W., Passed Assistant Surgeon. Directed to report to the Bureau, Washington, D. C., for special temporary duty, upon completion of which to rejoin his station, in Baltimore, Md.

SCOTT, E. B., Pharmacist. Granted leave of absence for two days, from April 11, 1908.

STIMPSON, W. G., Surgeon. Directed to assume temporary charge of Port Townsend Quarantine Station during

the absence of Passed Assistant Surgeon Oakley, on leave for one month from April 15, 1908.

WICKES, H. W., Passed Assistant Surgeon. Relieved from duty at Stapleton, N. Y., and directed to proceed to New Orleans, La., reporting to the medical officer in command of the Marine Hospital, for duty and assignment to quarters.

WILSON, R. L., Passed Assistant Surgeon. Relieved from duty at New Orleans, La., and directed to proceed to Cairo, Ill., assuming command of the service at that port.

#### Board Convened.

A board of medical officers was convened to meet at Seattle, Wash., April 13, 1908, for the physical examination of an alien. Detail for the Board: Passed Assistant Surgeon M. W. Glover, chairman; Assistant Surgeon C. W. Chapin; Acting Assistant Surgeon F. R. Underwood, recorder.

### Army Intelligence:

*Official list of changes in the stations and duties of officers serving in the medical department of the United States Army for the week ending April 18, 1908:*

ASHFORD, B. K., Captain and Assistant Surgeon. Ordered to report at Army Medical Museum Building, Washington, D. C., for examination for promotion.

CARSWELL, R. L., Captain and Assistant Surgeon. Left Depot of Recruits and Casuals, Angel Island, Cal., on leave of absence for two months.

CHAMBERLAIN, W. F., Captain and Assistant Surgeon. Ordered to report at Army Medical Museum Building, Washington, D. C., for examination for promotion; granted leave of absence for one month and ten days, with permission to ask an extension of twenty days.

DELOFFRE, S. M., First Lieutenant and Assistant Surgeon. Ordered to report at the expiration of his leave of absence at the Army Medical Museum Building, Washington, D. C., for examination for advancement.

FORD, J. H., Captain and Assistant Surgeon. Ordered to report at the Army General Hospital, San Francisco, Cal., for examination for promotion.

LAGARDE, L. A., Lieutenant Colonel and Deputy Surgeon General. Granted leave of absence for two months.

PAGE, Henry, Captain and Assistant Surgeon. Ordered to report at the Army General Hospital, San Francisco, Cal., for examination for promotion.

POWELL, J. L., Lieutenant Colonel and Deputy Surgeon General. Left Fort Ethan Allen, Vt., on leave of absence for ten days.

SCHREINER, E. R., Captain and Assistant Surgeon. Ordered to report at the Army General Hospital, San Francisco, Cal., for examination for promotion.

TRUBY, A. E., Captain and Assistant Surgeon. Ordered to report at the Army General Hospital, San Francisco, Cal., for examination for promotion.

WHALEY, A. M., First Lieutenant and Assistant Surgeon. Ordered to Jackson Barracks, La., for temporary duty; on completion, to return to station.

WILSON, W. H., Major and Surgeon. Returned to Fort Hamilton, N. Y., from accompanying troops to San Francisco, Cal.

### Navy Intelligence:

*Official list of changes in the medical corps of the United States Navy for the week ending April 18, 1908*

BROWN, H. L., Passed Assistant Surgeon. Detached from the naval station, Cavite, P. I., sailing from San Francisco, Cal., about May 5th.

CHAMBERS, W., Assistant Surgeon. Ordered to the Naval Hospital, Philadelphia, Pa.

DICKSON, S. H., Medical Inspector. Detached from the navy yard, Norfolk, Va., and ordered to the marine barracks, Washington, D. C.

ELY, C. M., Passed Assistant Surgeon. Detached from the naval recruiting station, Buffalo, N. Y., and ordered to the *Hartford* when commissioned.

HAINES, B. F., Acting Assistant Surgeon. Resignation accepted, to take effect April 15, 1908.

LANGHORNE, C. D., Surgeon. Detached from the marine barracks, Washington, D. C., and ordered to the naval station, Honolulu, H. I., sailing from San Francisco, Cal., about May 5th.

LEACH, B., Surgeon. Ordered to the *Hancock*.

MCDONELL, W. N., Passed Assistant Surgeon. Detached from the *Hancock* and ordered to the naval recruiting station, Buffalo, N. Y.

MCLEAN, A. D., Passed Assistant Surgeon. Detached from the navy yard, Portsmouth, N. H., and ordered to the *Chester* when commissioned.

SHIFFERT, H. O., Passed Assistant Surgeon. Detached from duty at marine at Camp Elliott, Isthmian Canal Zone, and ordered home to wait orders.

SMITH, C. G., Passed Assistant Surgeon. Detached from the naval station, Honolulu, H. I., and ordered home to wait orders.

STERNE, C. F., Assistant Surgeon. Ordered to the Naval Hospital, New York.

## Births, Marriages, and Deaths.

### Married.

FELLOWS—LOVE.—In Des Moines, Iowa, on Wednesday, April 8th, Dr. Joseph T. Fellows and Miss Estelle Love.

GEYSER—HIGBIE.—In New York, on Wednesday, April 15th, Dr. Albert C. Geyser and Dr. Annie S. Higbie.

HALL—PAGE.—In Brookline, Massachusetts, on Wednesday, April 22d, Dr. Gardner Wells Hall and Miss Elizabeth Hancock Page.

JONES—AUSTIN.—In Philadelphia, on Wednesday, April 22d, Dr. Isaac H. Jones and Miss Emily L. S. Austin.

PETTY—MELLERSH.—In Philadelphia, on Wednesday, April 8th, Dr. Orlando H. Petty and Miss Marcie Mellersh, daughter of Dr. A. H. Mellersh.

SAVAGE—INGERSOLL.—In New York, on Saturday, April 11th, Dr. William B. Savage, of Central Islip, and Miss Adele L. Ingersoll.

SCHULTZ—LIST.—In Philadelphia, on Wednesday, April 15th, Dr. Howard F. Schultz and Miss Maud List.

STRAETEN—ROOT.—In Washington, D. C., on Saturday, April 11, Dr. Renier J. Straeten, United States Navy, and Miss Emeretta Root.

SYKES—BERGAN.—In Philadelphia, on Wednesday, April 15th, Dr. Henry Sykes and Miss Elizabeth M. C. Bergan.

VOGT—NICHOLS.—In New York, on Wednesday, April 8th, Dr. William H. Vogt, of St. Louis, Missouri, and Miss Edna Jeanette Nichols.

### Died.

BROWN.—In Georgetown, Kentucky, on Monday, April 13th, Dr. George O. Brown, aged sixty-seven years.

CLISBE.—In Coldwater, Michigan, on Tuesday, April 7th, Dr. Stephen H. Clisbe, aged sixty-five years.

CROOK.—In New York, on Thursday, April 16th, Dr. James King Crook, aged forty-nine years.

CRUMB.—In Norwich, New York, on Thursday, April 16th, Dr. De Witt Crumb.

GOODMAN.—In St. Catherine's, Ontario, Canada, on Thursday, April 9th, Dr. Edwin Goodman, aged seventy-five years.

GORE.—In Charlotte, North Carolina, on Thursday, April 9th, Dr. J. W. Gore.

HUBBARD.—In Essex, Connecticut, on Sunday, April 12th, Dr. Charles H. Hubbard, aged seventy-two years.

KELLAR.—In Lexington, Kentucky, on Thursday, April 9th, Dr. David Kellar, aged eighty-nine years.

KENNEDY.—In Springfield, Massachusetts, on Friday, April 10th, Dr. Catherine M. Kennedy, aged sixty-four years.

LA COUNT.—In Wausau, Wisconsin, on Sunday, April 12th, Dr. David La Count, aged seventy-nine years.

LEWIS.—In Huntsville, Alabama, on Saturday, April 4th, Dr. P. H. Lewis, aged eighty-five years.

MCDOWELL.—In New York, on Wednesday, April 15th, Dr. Alexander B. McDowell, aged forty-four years.

RICHARDS.—In Glastonbury, Connecticut, on Friday, April 10th, Dr. George C. Richards.

ROBIE.—In New York, on Wednesday, April 15th, Dr. John Wilson Robie, aged seventy-one years.

THOMPSON.—In Boston, on Saturday, April 11th, Dr. George E. Thompson, aged fifty-nine years.

WADE.—In Danbury, Connecticut, on Saturday, April 11th, Dr. J. Alexander Wade.

#### A BRIEF CRITICAL REVIEW OF A YEAR'S PROGRESS IN TROPICAL MEDICINE.\*

BY JAMES M. ANDERS, M. D., LL. D.,  
Philadelphia,

Professor of Medicine and Clinical Medicine in the Medical College; Consulting Physician to the Jewish Hospital; Consulting Physician to the Widener Home for Crippled Children, etc.

It has been an honor, highly appreciated, to serve as the presiding officer of a body so distinguished as that of the American Society of Tropical Medicine during the year just ended. Before taking up the theme of my brief discourse, I desire to convey to the officers, more particularly to the efficient secretary, Dr. Swan, whose enterprise deserves unstinted praise, my grateful acknowledgment of the singular zeal manifested in the executive work of this society. Especial commendation is also due the members for increased activity and greater fruitfulness of results in the individual study of tropical affections during the past year. The growing importance of this special field of medicine is becoming rapidly evident, and it is equally clear that a thorough and systematic investigation of this class of diseases in the immediate future is vital to the progress of medical science and art in America; and to appreciate this truth it is only essential to grasp the changed conditions—social, industrial, hygienic—growing out of the acquisition of our new dependencies.

The present state of affairs has already called forth a practical rearrangement of the themes pursued, and labors of, governmental officials, sanitarians, clinicians, and research workers. But the present activities in the domain of tropical medicine may be regarded as being but a feeble foretaste of what the future inevitably conceals. Tropical diseases have been among the last to engage the serious attention of trained scientific investigators, although many members belonging to this extensive group have been imperfectly known and described from the remotest antiquity. Among the influences that will count for much in determining the extent and nature of this work to be carried forward in the immediate future for the better service of our science and art, the American Society of Tropical Medicine should, and doubtless will, take conspicuous rank. If I mistake not, this new society, with the light of dawn still upon it, is gripped with a

high purpose, and destined to fulfil its great promise.

In devoting attention to the elucidation of the subject, the undertaking should have reference to well defined points of view—e. g., ætiological, pathological, clinical, therapeutical. In order to achieve satisfactory and permanent results, these different phases should receive separate consideration, although an intimate and practically important interconnection between them must be recognized. The earlier work should aim to obtain sure ætiological and pathological facts or evidence, for in the absence of a knowledge of the necessary causes of tropical diseases and a clue from their pathology we shall continue to remain ignorant of, or, at all events, incapable of interpreting their clinical behavior. On the other hand, systematic, uniform, and properly directed investigations cannot fail to achieve much needed information available for practical uses.

In the case of the infective diseases, at all events, the practical solution of the issues involved must come from ætiology and pathology. No large measure of professional opinion, expressed or entertained on any medical subject can receive adequate support either from clinical observation or therapeutical tests alone. Considerable thought, therefore, should be given to the order of development of the vast field of research in question, and to the thread of connection between the different aspects of the complicated subject.

This, then, is the pathway to be trodden, my learned coworkers, if we would venture to hope to bring this extensive field of investigation into that state of forwardness which characterizes our positive knowledge of many nontropical diseases. Much has hitherto been discovered and announced to the scientific world, but more is still enveloped in obscurity, to be elucidated, as intimated before, by appeals to bacteriology, parasitology, morbid anatomy, and morbid physiology, through the aid of which the clinical symptoms manifested may be rationally interpreted.

Whilst the year just ended has witnessed but few, if any, epoch-making discoveries, the net gain may be said to have been considerable, and is an augury warranting the most favorable predictions for the future. It is to be recollected that the magnitude and complexity of the problems awaiting solution can scarcely be appreciated by an enlightened profession, as yet imperfectly acquainted with the manners, habits, and customs of the peoples of our newly acquired territories.

To attempt to give a complete review of the pro-

\*Address of the president delivered at the Annual Meeting of the American Society of Tropical Medicine, held at the Hotel Hamilton, New York, March 28, 1908.

gress actually made during the previous year would lead beyond the scope of this address: I shall, therefore, be constrained to content myself with a brief chronicle of the more important advances gained during that short period of time. Mere theoretical expressions, unsupported by proof, will be rigorously omitted.

Foremost among tropical affections comes plague, and magnificent recent work has been done in relation to the ætiology, more especially the modes of conveyance of the bacillus. The recognition of the fact that the plague bacillus may be carried from one rat to another by the rat flea resulted from the labors of the British Plague Commission working in India.<sup>1</sup> During 1907, the previous experiments of the commission have been entirely confirmed, and additional observations, which have contributed much to systematic science, have been conducted.<sup>2</sup>

It was conclusively shown that rats could be infected by feeding them with the viscera of dead plague rats, and that in such cases the site of the bubo was the mesentery. *Per contra*, cervical bubo is the rule in naturally infected rats, hence it is obvious that natural intestinal infection rarely, if ever, occurs. Evidence to show that the infected faces of the flea may carry the infection to the flea bite sustained by man has been advanced.

It was proved that the Indian rat flea (*Pulex cheopis*), under certain circumstances, will readily bite man—a fact which has long been the subject of controversy. Rothschild has pointed out that this species of flea is the commonest one found on house and port rats in many parts of the world, and that it is identical with the *Pulex palidus* found in Australia and the *Pulex philippinensis* found in Manila—localities where plague has repeatedly appeared. The *Pulex irritans* and *Ceratophyllus fasciatus* were also shown by experiment to be capable of infecting animals in a few instances, and it is of prime importance that their exact influence in the transmission of plague from rat to man should also be determined.<sup>3</sup>

So strongly has the entire medical profession become impressed with the truth of the view that the principal, if not the only, means of transmission has been accurately determined to be the flea, that no invincible obstacle to the serious business of the United States Public Health and Marine Hospital Service and State and municipal authorities in applying antiplague measures will, it is hoped, be permitted to exist in future. Granted that every facility be provided for the operation of these organized bodies, the impracticability of absolute prevention must, owing to the peculiar mode of transmission, appear evident. Finally, the necessity for united action with a view to exterminating rats and fleas in infected localities will be universally acknowledged.

Haffkine<sup>4</sup> has recently described the present position of inoculation in an important address delivered to the Epidemiological Society of London on the Present Methods of Combating Plague. His conclusions were:

1. "The races of Indians more susceptible to plague than Africans, Europeans, and some other races, but the inoculation treatment reduces the liability to attack to less than one-fifth of that in non-inoculated." 2. "In one-third of the

cases which occur in the inoculated the recovery rate is at least double that in the noninoculated, the ultimate result being a reduction in the plague mortality by about 85 per cent. 3. All the cases of plague in inoculated Europeans have ended in recovery. 4. Inoculation is applicable to persons already infected and incubating the plague and prevents the appearance of symptoms, or else mitigates the attack. 5. In natives of India the degree of immunity conferred by inoculation, though it gradually diminishes, lasts during several outbreaks of the plague. 6. In Europeans the effect has not yet been seen to disappear since its introduction in 1897.

Reference should be made to the exhaustive studies of Richard Strong<sup>5</sup> in plague immunity. This observer doubts the protective value of Haffkine's prophylactic, while certain Indian physicians emphasize its great value in lessening plague incidence and plague mortality. For example, W. J. Simpson,<sup>6</sup> in the Croonian Lectures on plague, stated that one injection of three cubic centimetres of Haffkine's prophylactic is sufficient to protect during an existing epidemic:

Inoculation is powerless to arrest the disease in those in whom the symptoms have already appeared or develop in a few hours after inoculation. Inoculation mitigates or aborts the disease in those who are in the incubation stage or have been infected three or four days previously.

Strong advocates the injection of attenuated living cultures of *Bacillus pestis* as a method of immunization. He found natural plague aggression effective in animal experiments, but owing to the great difficulties encountered in its preparation this will probably not be generally adopted. Strong also demonstrated the fact "that the development of the immunizing substances is quite independent of that of the agglutinins." Strong arrives at the conclusion that in sera possessing immunizing power no bactericidal action can be shown to exist. He insists that inoculation against plague with suitable cultures is not infallible on account of individual variations in susceptibility to infection and in natural resistance. There is a consensus of opinion that inoculation is powerless to influence the general course of the disease after it is well characterized clinically.

The work of Ashburn and Craig,<sup>7</sup> in connection with *Filaria philippinensis*, is especially worthy of notice, and among the conclusions reached are the following: (a) That the complete development of *Filaria philippinensis*, discovered by them in 1906, has been followed in the mosquito, *Culex fatigans*; (b) that the *Filaria philippinensis* is distinguishable from other filariæ "both in the blood and during the developmental cycle within the mosquito"; (c) that as regards the time of its occurrence in the blood, this organism presents no periodicity. The same observers have, by their persistent investigations into the ætiology of dengue, thrown an important sidelight upon that subject. Of their conclusions, a few merit enumeration here:

(a) The specific cause is most probably ultramicroscopic in size, neither bacterium nor protozoon being demonstrable in either fresh or stained specimens of dengue blood by the microscope or in bouillon blood culture; (b) the disease is characterized by a well marked leucopenia, the polymorphonuclear leucocytes being decreased, as a rule,

while the small lymphocytes are decidedly increased; (c) dengue can be transmitted by the mosquito, *Culex fatigans*, hence it is probably not contagious, but infectious in the same manner as is yellow fever and the malarial fevers. It should be pointed out that Schaudinn, Novy, and others suspect that both dengue and yellow fever are caused by protozoan parasites.

Musgrave<sup>9</sup> has observed seventeen cases of paragonimiasis, eight of which came to necropsy, in Manila, during the year 1906 and the early part of 1907; he has contributed an exhaustive study of this infection, based partly upon the post mortem findings and partly upon close clinical studies of the cases observed. The course of the disease is usually chronic, although an acute form is recognized with secondary infection, as a rule. Again, the condition may be either generalized or localized. An assured diagnosis rests solely on the finding of the ova of the trematode in the sputum, in the feces, the scraping from ulcers, or in fluids and tissues removed at operations. Until more is known of the life history of this parasite, satisfactory prophylactic measures cannot be indicated. The subject is of distinct importance to this body, since imported cases have been met with in the United States and will probably be more commonly found in the future.

Concerning the ætiology of yellow fever, the results of recent investigations, while failing to demonstrate the presence of any organism having ætiological significance, are strongly suggestive that the disease is due to a spirochæta. In the *Public Health Reports* for May 3, 1907, Stimson describes an organism which he observed in the kidney of a yellow fever patient, following the method of Levaditi, its general appearance suggesting a spirochæta. But though specificity cannot be assigned to this organism, without ample confirmation, it is undoubted that the blood picture closely resembles that of diseases known to be caused by protozoan parasites.

During August, 1907, a few cases of yellow fever were reported from Cuba, but, as was to be expected, no widespread epidemic was kindled thereby. An important lesson is taught the medical profession by these recurring outbreaks of yellow fever and other infectious diseases; it is that the final eradication of pestilential diseases is practically beyond human power. Again, such visitations indicate clearly enough the necessity for constant vigilance or the constant application of active measures calculated to serve as preventives, more particularly in the warm months or period of the year during which our territory is continually menaced.

Professional zeal, amounting to anxiety, to learn the specific cause of that interesting form of multiple neuritis, beriberi, has failed to receive an encouraging impetus within the past year; both the bacillus of Hamilton Wright and the cocci of Okata and Kokubo have been shown to bear no ætiological relation to the disease. The ætiological position of the organism discovered by Tazizuki<sup>10</sup> still lacks the needed experimental proof.

Hewlett and de Korte<sup>11</sup> have advanced a new

tentative hypothesis, namely, that beriberi is the result of a protozoan infection, the invasive agent being eliminated through the urine, which conveys the contagion. In the urine of beriberi patients were found three varieties of refractive cells, believed to be degenerate cells, or protozoa. These observers also carried out investigations bearing on the pathology of beriberi. They found a disease in monkeys showing marked similarity to beriberi; the animals were anæmic, the knee jerks either exaggerated, diminished, or absent, with œdema of the face and genitalia in some cases. The urine showed hyaline casts and highly refractive cells (supposedly protozoa), but no albumin. The animals succumbed to the disease, and post mortem section revealed changes similar to those met with in the human kidneys in this disease.

In the recent past numerous excellent articles concerning the ætiology and nature of beriberi have appeared in medical literature. There are not a few modern writers who contend that the disease is of dietetic origin, more particularly from the ingestion of rice and fresh fish. While the controversy as to whether beriberi is a microorganismal disease or the food theory is to be ultimately accepted, the balance of testimony would appear to be favorable to the infectious nature of the disease, although it must be owned that the specific cause still remains in doubt.

Among the advances in experimental therapeutics is to be mentioned the use of vaccine prepared from cultures of *Micrococcus melitensis* freshly isolated from the spleen during life. Bassett-Smith<sup>12</sup> reports two series of cases, the first series consisting of twenty-two cases, with marked improvement in fifteen, the second consisting of twenty-three patients, with marked improvement in sixteen. He restricted its use to the more chronic condition, in which there was a mild, seasaw temperature without marked hectic symptoms. Fortunately, although Malta fever is regarded as an acute infection, most cases pursue a chronic course. It is important to recollect that the addition of further quantities of artificially produced toxine to a patient in the acute phases of an infectious process is likely to act detrimentally. In view of the results thus far obtained, the method of treatment under consideration deserves more extended trial.

During the past year the bacteriologists have continued to bestow much attention upon the subject of the ætiology of intestinal diseases, attended with the symptom complex, known as dysentery. Ashburn and Craig,<sup>13</sup> in a study of tropical diseases as they occur in the Philippine Islands, report, under date of June 15, 1907, that they have examined one hundred healthy men, of which seventy-two, or seventy-two per cent., have shown *Entamoeba coli* in their feces. These men were all American soldiers serving at the division hospital, Manila, P. I., with no dysenteric symptoms since residing in the Philippines. They contend that it is possible to distinguish *Entamoeba coli* as they occur in the feces of

<sup>9</sup> *Memoria International de Neurologia*, R. Medical Sciences, March, 1908.

<sup>13</sup> *Ibid.*

man, from the morphological appearance of the amœba, and cite two cases which were fully corroborated by information concerning their previous history, elicited subsequent to the bacteriological examinations.

Dr. Jesse Weston Fisher<sup>14</sup> has recently made a bacteriological study of normal and diarrheal stools for the detection of organisms belonging to the dysentery group; he employed thirty-seven patients. Of these eighteen were healthy, and nineteen suffered from mild diarrhoea. The evidence, as it stands from these investigations, leaves little room for doubting that diarrheal cases in which blood or bloody mucus are found in the stool, all show the presence of the *Bacillus dysenteriae* of the Flexner type. Thus but two exceptions of mild grade were noted in Fisher's series; one of these showed a bacillus of the Shiga type and the other of the Duval lactose fermenting type. It is worthy of notice that the Shiga type may be the exciting cause of mild diarrhoeas, but it is not found in normal stools. On the other hand, a "dysentery like organism" called *Bacillus F.* was recovered from 44.4 per cent. of normal stools, "from the stools of 10.5 per cent. of cases of simple diarrhoea, and from the stools of 0.01 per cent. of cases of dysentery." This organism was found to inhibit the growth of both the Shiga and Flexner types of *Bacillus dysenteriae* in test tube cultures, and in agglutination and absorption experiments the organism produced specific agglutins for itself, but not for types of dysentery, colon or typhoid.

Two cases of gangosa—a destructive ulceration and gangrenous disease of the palate and nose—have been reported within the past year, one by Stitt,<sup>15</sup> observed at a naval hospital at Canacoa, and the other (a fatal case) by Musgrave and Marshall,<sup>16</sup> occurring in a male Filipino, who had never been away from the island of Luzon. A bacteriological examination of the scrapings from the lesions proved negative in its results. Musgrave and Marshall give the details of the histological examination of the tissues; they regard the condition as distinct from syphilis, yaws, and tuberculosis, although finding themselves on difficult ground, owing to the absence of any organism having ætiological significance, a positive expression of opinion is wisely withheld.

Since the recent publication of the article by Yount and Sudler<sup>17</sup> on the subject of human myiasis from the screw worm fly, considerable interest has been awakened in the subject. The disease is believed to be not rare, and the twenty-three cases reported by the authors occurred during a single summer. In man its results are always serious or fatal if not early and properly treated. The disease attacks many lower animals—e. g., horses, cattle, sheep, hogs, and it has been observed in many countries, islands of America, North America, Cuba, Mexico, Brazil, Venezuela, Chile, and New Holland. According to Snow, it is common from Argentine Republic to Canada. In the vast majority of cases, the site of the attack is the nasal

mucosa, where it produces ulceration often associated with necrotic or gangrenous changes.

These observers point out that "a chronic rhinitis or otitis or even uncleanliness attracts the female fly, as does any exposed wound or ulcer." It is also noteworthy that sleeping in the open air gives the fly an opportunity to deposit its eggs, after which the larvæ are capable of boring into healthy as well as diseased tissue. Yount and Sudler present the symptomatology and diagnosis of the condition in the article referred to, and it is interesting to observe that chloroform employed in the form of a spray is counselled for diagnostic purposes, as it serves to bring the parasites to light, and also as the most effective measure of treatment.

Among the more important tropical and sub-tropical diseases stands uncinariasis, which has received a large share of professional attention, and the recent work of E. C. Shattuck,<sup>18</sup> of Manila, on this disease is worthy of elaborate mention. The hospital system, consisting of Bilibid Prison, with 3,800 prisoners, a hospital of 150 beds for general purposes, and a quarantine pavilion in which all recent admissions to prison are kept for a period sufficient to develop any latent infection, furnished ample opportunity and scope for systematic and satisfactory observation. All new admissions were regularly examined for intestinal parasites, and appropriate treatment instituted in infected cases.

Approximately 1,000 examinations of quarantine cases have been made to date. Of 530 prisoners admitted to the hospital for treatment, there were 243 cases of uncinariasis, sixty-three of amœbic dysentery, three of *balantidium coli* infection, 186 of ascariis infection, seven of tenia, and the remainder acute dysentery.

There is a tangible basis for the belief that thorough, careful observations on this broad line will lead to the discovery of points of great interest and importance for practical purposes. As Shattuck pertinently remarks, however, the work on uncinariasis is hardly more than begun, although the prompt recognition of the condition, from the microscopical examinations referred to before, has doubtless already contributed materially to the marked decrease in the death rate during the past half year. Extended investigations have been carried out simultaneously in connection with the treatment, and as the result preference is given to eucalyptus rather than thymol, which was formerly the generally accepted remedy.

Authors are in agreement that prevention of uncinariasis must lie in two directions: First, personal cleanliness, and, second, the prompt disinfection of the faeces. Of less, though considerable import, is the question of the prevention of faecal deposits in moist places and near to dwellings.

In the recent work on *Anæmia in Porto Rico*, by the Permanent Commission for the Suppression of Uncinariasis, it is estimated that ninety per cent. of the population suffers from this formidable scourge. The Commission treated 89,233 patients with the following result: Complete cure in 25.71 per cent.,

<sup>14</sup>Journal of Medical Research, May, 1907.

<sup>15</sup>Philippine Medical Bulletin, July, 1907.

<sup>16</sup>Philippine Journal of Science, August, 1907.

<sup>17</sup>Journal of the American Medical Association, December 7, 1907.

<sup>18</sup>American Medicine, December, 1907.

practical cure in 17.88 per cent., and 40 per cent. are still under treatment. Of those treated, 0.21 per cent. died. The treatment consisted in the repeated administration of thymol and betanaphthol, preceded and followed by a saline. Eucalyptol was tried, but was not found efficacious. At autopsies renal degeneration rather than inflammatory lesion was found.

An International Conference on Sleeping Sickness was held in London (June, 1907), and it is a matter of deepest regret that its deliberations and reflections can merely be touched upon in this place. Among the conclusions arrived at, based on present knowledge of the subject, is that sleeping sickness is due to the *Trypanosoma gambiense*, "propagated in main by the *Glossina palpalis*, or tsetse fly, although other species of flies, notably of the glossinæ, cannot be excluded."<sup>2</sup> Methods of prevention concerning both the patient and the fly were suggested and considered, and among the most noteworthy are: Police sanitation of infected individuals in order to prevent the transportation of the parasite, the avoidance of the establishment of camps or habitations in localities where the tsetse fly lives, particularly to keep clear of infected localities, attention to the borders of streams and lakes (clearing out the brush, etc.), the places inhabited by the flies, and, finally, the protection of houses, closets, etc., by mechanical means in order to keep out both glossinæ and various species of anopheles. From the therapeutic side, the conference approved the use of arsenic, which, by diminishing the number of trypanosomes in the blood, also diminishes the chances of contagion. Koch<sup>3</sup> has suggested that trypanosomiasis may be transmitted by sexual intercourse.

The formation of the International Society of Tropical Medicine during the Fourteenth International Congress of Hygiene and Demography, which was held in Berlin in September, 1907, was an event well worthy the serious notice of this society. The objects of the society are twofold: First, to bring together the societies of tropical medicine of different countries for the purpose of an exchange of views, and, second, to hold a congress of tropical medicine once in three years.

The affairs of the international society have been in the hands of a committee of management, composed of two representatives of each national society of tropical medicine, and the authorized members on said committee from the United States are Dr. H. G. Beyer, of the Navy, and Dr. Richard P. Strong, of the Government Biological Laboratories at Manila.

Mention should also be made of the establishment of two new journals, namely, *The Annals of Tropical Medicine and Parasitology*, published by The Liverpool School of Tropical Medicine, of which the first number was issued under date of February 1, 1907, and *The United States Naval Medical Bulletin*, published in Washington, the first number appearing in April, 1907.

1005 WALNUT STREET.

## SOME THOUGHTS ON THE ÆTIOLOGY, PROPHYLAXIS, AND TREATMENT OF THE SOCIAL ILL.\*

By S. ADOLPHUS KNOPP, M. D.,  
New York.

As the title of my paper indicates, I have no intention to present to you suggestions for the complete solution of this momentous problem. All I expect or can hope to do is to call the attention of this audience to a few perhaps less known ætiological factors and point out some measures which, to my mind, may be added to those already in vogue in the prevention and treatment of this ill.

First, let me explain, not exactly as an apology for, but rather in defense of the innovation of speaking of the problem of prostitution; not, as is usually done, as a social evil or social crime, but simply as a social ill.

The general understanding of the word "evil" implies that the perpetrator of the act which is supposed to be an evil one is an evildoer or criminal. I believe it is neither just, humane, nor even consistent to call the offenders, male or female, criminals in every instance. Before an audience of this kind I do not need to state that there are numerous cases in which the unfortunate woman is really innocent, if not before the laws made by man, at least before the higher divine laws. That there are also instances when the other sex, the innocent and unknown youth, has fallen victim to the experienced, unscrupulous courtesan, often old enough to be his mother, is also too well known to need detailed mention.

When not applied to physical conditions, the word evil is usually understood as wicked conduct or criminal disposition, while the word ill or illness, when figuratively used, means a derangement and an unwholesome condition. By rights we should not even call prostitution *the* social ill, but only *a* social ill, as it is by no means the only one, for surely alcoholic intemperance and gambling must also be considered social ills responsible for fully as much misery as prostitution.

Presuming, then, that you will grant me the privilege of substituting the name "social ill" for "social evil," what definition would I wish to give of this term in order to convey in concise words my reasons for the change? I would say the social ill is an abnormal, or, figuratively speaking, a pathological condition which results from disturbances or failures of sociological functions of the individual, for which in few instances the individual alone, but in the majority of cases our social fabric, is responsible.

Let us now trace for a few moments some of the ætiological factors perhaps not usually or not sufficiently thought of by reformers. I cannot nor will I subscribe to the cruel statement made by some sociologists and syphilographers that many women are born prostitutes. There is no evidence for this assumption. All physicians know, of course, that just as there are boys born with an adherent prepuce, so are there girls born with an adherent clitoris. When these trifling physical defects are not

\*International Article, *New York Medical Journal*, September 11, 1907.  
<sup>2</sup>*Journal of Tropical Medicine and Hygiene*, February 1, 1908.

\*Read before the American Society of Sanitary and Social Prophylaxis, April 9, 1908.

corrected they may lead to the habit of masturbation in both sexes. When operated upon, the acquired pernicious habit usually ceases. But if, as is asserted by some authorities, this physical defect predisposes the female child to prostitution and the male child to corresponding abnormalities, then by all means let us make it a practice to have every child, male or female, carefully examined and treated for such possible defects by a competent physician.

Physicians of public nurseries, orphan asylums, boarding schools, etc., should make it a rule to examine every child under their care for possible defects or deformities which, when left uncorrected, might destroy the moral conception of what is right and wrong sexually.

We are educating in this country every year a goodly number of women physicians who should be best fitted for such work in girls' institutions, particularly when it is extended, and it should be to all public schools.

Hysteria is another disease, which, according to some authors, is predisposing to prostitution. Le-grand du Saulle observed that twelve per cent. of hysterical women took to prostitution out of sheer dilettantism, without any pressure from misery, and, according to Tarnowsky, the percentage is as high as fifteen per cent.<sup>1</sup> If that is true then let us examine every female child and treat it thoroughly for whatever hysterical manifestations may show themselves.

What other classes of children are there who, because they often enter the life of prostitution at the age of puberty, if not before, are for that reason classed by certain writers on the subject as born prostitutes? They are the unfortunate little ones born amid surroundings of ill repute or vice. While in such instances it cannot be denied that a predisposition to the social ill under consideration may be acquired, one can and should not speak even here of a born prostitute. This is shown by the very fact that many a woman whose lot has been cast among these unfortunate ones, on becoming a mother has often worked and sacrificed herself so that she might give to her offspring the chances of a purer and better life by placing the child in an institution or a responsible private home. A great many prostitutes are recruited among the children of widows and deserted wives, and perhaps an equally large number from children whose parents are incapable, shiftless, or dead.

In New York city we have a number of local charitable agencies intended to relieve misery caused to wives and mothers by the death or desertion of their husbands, but to find a truly far reaching remedy for these conditions we must look to the example of New South Wales. In that advanced community there exists a State Children's Relief Board, whose purpose it is to protect, first, the child without a parent; secondly, the child with an irresponsible, immoral, or wholly incapacitated parent. With the aid of the Children's Relief Act, the future citizens of New South Wales, male and female, who are deprived of the benign influence of intelligent and loving parents, are disposed of by being boarded with selected foster parents. If the mother

is a widow or a deserted wife she retains the children as boarders, an allowance from the State enabling her to do so until they have become self supporting.

I come now to one of the most painful subjects, which must be considered a strong ætiological factor of prostitution. I refer to that other horrible social ill which I have not yet mentioned, child labor. Permit me in regard to this to quote from John Spargo's book, *The Bitter Cry of the Children*:

The moral ills resulting from child labor are numerous and far reaching. When children become wage earners and are thrown into constant association with adult workers, they develop prematurely an adult consciousness and view of life. About the first consequence of the employment is that they cease almost at once to be children. They lose their respect for parental authority in many cases, and become arrogant, wayward, and defiant. There is always a tendency in their homes to regard them as men and women as soon as they become wage earners. Discipline is at once relaxed, at the very time when it is most necessary. When children who have just entered upon that most critical period of life, adolescence, are associated with adults in factories, are driven to their tasks with curses, and hear continually the unconstrained conversation, often coarse and foul, of the adults, the psychological effect cannot be other than bad.

In saying this I would not for a moment desire to cause a reflection on the general character of the working women or men within or without the factory. I believe their moral standard compares favorably with that which we call society. But with Mr. Spargo I say that for the plastic and impressionable mind of a young girl between the ages of ten and fifteen the moral atmosphere of the average factory is bad, and I know that none will more readily agree with us than the men and women who have worked in mills and factories.

But leaving aside the possible corruption of the child's mind, let us turn for a moment to the other features of child labor. Take a little girl of ten years of age, put her to work in a factory for ten hours a day, and let her live this humdrum existence to the age when she develops into womanhood, will she be able to resist the temptation of a life of ease and plenty if it is offered to her? That parents who make of their daughters slaves by enforcing child labor at home, by depriving them of their natural rights to play and recreation, compelling them to mind for hours and hours the smaller children, do house and kitchen work when not at school, are equally responsible for many a young girl becoming wayward and seeking freedom in what she thinks is a happier and more joyful life. Undue severity with children, especially with young girls, is as much to be condemned as lack of all discipline.

That great reformer and lover of children, Judge Lindsay, of Denver, has told us what not to do with children when they are seemingly in the wrong: "Do not punish a child at the time of offense; wait and cool down, otherwise you make yourself ridiculous and the child will fail to get justice." "Do not mistrust a boy or girl even if your confidence in him or her is weak; faith will work wonders." "Do not talk roughly or swear at a boy or girl; it is a trick of a coward."

We must do away with child labor in factories as well as at home. The excuse of some advocates of child labor, that the money the children earn is

<sup>1</sup> *Journal of the American Medical Association*.

needed to supplement the meagre earnings of the father, is rarely well founded. In the few instances where child labor seems to be necessary to help support the family our local Consumers' League comes to the rescue by according scholarships to the children.<sup>2</sup> On the other hand, in most communities where there has been enforcement of child labor laws, investigation has proved that in families where the father was sober and industrious child labor was not needed.<sup>3</sup> By saying this, however, I do not wish to exclude the, alas, quite numerous instances where the heads of families who are workers are underpaid. It is also true that if we could but convince working men and women that the intemperate use of alcoholic drinks is responsible for a great deal of their misery, privation, and want, the laboring man would be helped to make himself, his wife, his sons, and daughters happier, better, and nobler citizens.

It would lead too far to discuss here at length the second social ill, "alcoholism," the curse of our and so many other nations. We know that the excessive indulgence of alcohol dulls the moral senses of man and woman, and the child of an alcoholic parent is apt to become itself an alcoholic and inherit other stigmata of a degenerate type. Thus alcoholism indirectly predisposes to the social ill.

What remedy have I to suggest for the combat of alcoholism in order to combat the social ill at the same time?

Some time ago it was my privilege to read before the Society of Medical Jurisprudence a paper on the subject of Medicine and Law in Relation to the Alcohol, Venereal Disease and Tuberculosis Problems.<sup>4</sup> In it I suggested a few remedies to combat alcoholism, such as a law preventing the habitual drunkard from marrying, and the most rigid enforcement of the law which makes it a felony to sell liquor to a minor or to administer strongly alcoholic beverages to a child without the physician's prescription. The law which obliges the manufacturer of patent medicines to put on the label the exact alcoholic contents of the nostrum should be enforced with equal vigor. Rational educational movements instructing the people to be temperate in all things should be encouraged. And last but not least may I suggest an antitreaty club, so that when a drink must be taken in company with others, it should not, because of the time honored American custom, be multiplied according to the number of the company present.

I cannot help thinking that the establishment of more comfort stations would greatly reduce the necessity of many a man going into a saloon, where he feels obliged to take a drink in order to avail himself of the toilet facilities. There is no doubt in my mind that numerous sanitarily constructed and well kept comfort stations for both sexes throughout the city would greatly add to the physical comfort of many people and indirectly prevent a great deal of illness of all sorts. It is well known

that even syphilis and gonorrhoea have been transmitted to innocent adults and children because of badly and unsanitarily kept public comfort stations.

There should be more play, more sleep, and less work for our school children. I hold the highly nervous state of our children, which is produced by too much mental work at school and at home, and not enough sleep nor enough out door life, largely responsible for the readiness of our young people to acquire the alcohol habit.

Of the nefarious influence of child labor on the constitution of the growing girl and boy as a predisposing factor to the social ill I have already spoken. That a young man's or woman's nervous system, after being wrecked by child labor, is more ready to acquire the alcohol habit, with all its nefarious consequences, must also be evident. The seriousness of child labor in this country is, I am afraid, not well enough understood and appreciated. Let me hope that the gravity of the situation will be better understood by you when I tell you that, in spite of all the labors of many noble men and women, there are still, according to Mrs. Florence Kelly, the secretary of the National Consumers' League, well known for her noble work in this cause, no less than 2,000,000 children earning their living in factories and workshops in the United States.

Rational lessons in temperance should be taught in schools and adapted to the understanding of the child.

I believe in the Gothenburger system, which consists in the manufacture and sale of alcohol by the government, and giving the dispenser of alcohol a salary, so that no benefit shall accrue to him from the amount of alcohol he sells, but I fear this system is not as yet practicable in our country. Perhaps even a law limiting the manufacture of alcoholic beverages is not yet feasible, but I believe in the possibility of limiting the number of licenses of saloons and even elevate their standard by eliminating that type of saloons which police records show to be centres of crime. There should be State institutions for the treatment of alcoholism to which the habitual drunkard could be committed by law, and to which the man desiring to free himself from the craving for alcohol could commit himself voluntarily.

Bad housing, unsanitary and unclean, overcrowded tenements, with no room for the children to play or for young people to meet in innocent and wholesome enjoyments, and with no place for recreation for the adult, are factors in predisposing men and women, young and old, to both alcoholism and the social ill.

Who will dare to deny that the thin partition walls and the often promiscuous mixing of the sexes in the crowded quarters tend to the demoralization of the young girl blossoming into womanhood? It is my firm conviction that the building of more model tenement houses, where comfortable and healthy quarters can be obtained at the same and often more reasonable rates than are now demanded for rooms hardly fit for human habitation, the remodeling of bad tenements, the making an open playroom of the roofs of all tenements, old and new, by fencing them in with strong wire netting, the

<sup>2</sup>The amount of the scholarship is varied, equalling approximately what the child could earn if it were not for the fact that it is not permitted to work in the family saloons. These scholarships have been given to a number of our children, to enable them to attend the public schools and to secure credit in the receipt of a certificate of regular attendance from the school principal.

<sup>3</sup>See page 7, *The Father's Role in the Problem of Alcoholism*.

<sup>4</sup>*Medical Jurisprudence*, June 1, 1907.

creation of more parks and playgrounds within the most crowded sections of our city, and the establishment of healthy places of amusement, open Sundays and weekdays, where the laborer can partake of very light or nonalcoholic drinks and enjoy the society of his friends, will do more to do away with alcoholism and diminish the social ill than anything heretofore tried.

My studies in relation to tuberculosis and the housing problems in large cities, and particularly in our own, have, of course, convinced me that, with the constant increase of our population, the building of new tenements and the remodeling of old will not suffice to do away with all the congestion, the causes of tuberculosis, other diseases, and the social ill. Something in the line of the work of the Garden Cities Association of England and also of this country will have to be done on a large scale. For those who are not familiar with the object of this movement I wish to say in brief that its object is to advocate and to further the removal of families and individuals, particularly of the industrial and working classes, from overcrowded cities to the country, where each family may have its own comfortable home in surroundings and under conditions which shall unite, so far as possible, the attractions both of the city and of the country. To obtain this end, these associations work toward the founding and developing of model industrial towns and villages, or so called "garden cities," wherein factories, stores, and other forms of business may be established, with space for air, beauty, convenience, and room for growth.

To many of you this may seem a dream, but those who have visited the Congestion Exhibit last month and were privileged to listen on the opening evening to our distinguished governor's address, will grant me that I do not stand alone with this view of the solution of the congestion problem with all its attending evils and ills. If I understood Governor Hughes correctly, he said that night that distribution of the people in more tenements on the island would not in itself suffice, but that there must be also a large distribution of centres of work. Besides improving existing tenements in accordance with the tenement house law and building new model tenement houses on the still unoccupied and healthful sections of Manhattan Island and the neighboring boroughs, we should do all we can to encourage garden city movements. That even the city and State would be the financial gainers if they would come to assist in such enterprises, I hardly need to dwell upon before an audience which has made the study of social medicine its main object. The cost of wretchedness as it now exists is greater than would be the cost of prevention. To emphasize this still more let me repeat to you the exact words of the governor from that impressive address: "Who pays the bill? The city and the State are paying for the crime, for the disease, for the wretchedness that comes from those congested conditions."

The social workers in the districts of the poor will tell you that the disreputable dance halls are perhaps one of the greatest sources of danger to the young, unsophisticated girls of the tenement house districts. We have learned recently through our daily press that a vigorous crusade has been in-

augurated against these places, where many a young girl, often while yet in short skirts, has been enticed with fatal consequences.<sup>5</sup> All of us will endorse this crusade against such dangerous resorts, but must we not also think of the necessity of providing in their stead places of amusement where the young girl could safely go and be shielded from all danger? Young people love and need enjoyment; they love to dance and love to be merry. Let some philanthropist think of this, and by a munificent gift help the social settlements, the People's Institute, and similar institutions to enlarge their work in this field or create new fields for legitimate enjoyment and rational recreation for the young workers.

The next most important feature to be considered is, of course, education as a prophylactic means. To educate first the lawmakers where such education is still needed would seem of prime importance. I refer first to the wisdom of enacting laws such as are already in vogue in Michigan, which forbid the issuing of a marriage license to individuals afflicted with venereal disease, and, secondly, to the necessity of a federal law to make obligatory the instruction of recruits to the United States army and navy and pupils of naval and military academies concerning venereal disease, personal hygiene, etc. It is for the purpose of educating the masses, the young, the adolescent, and the adult regarding the sexual problem and the prevention of venereal diseases perhaps more than for any other reason that the American Society of Sanitary and Moral Prophylaxis has been founded.

You are all familiar with the fact that the prime mover in the magnificent work is the distinguished gentleman who presides over this assembly to-night, Professor Prince A. Morrow. He has not only given us the fruits of his lifelong experience as a physician and teacher, but has favored us at the very beginning of our career with a number of lectures,<sup>6</sup> here and elsewhere, which have been most helpful in starting such associations in other cities.<sup>7</sup> It is to be hoped that soon every city in the United States, nay even every hamlet of any size, will have such a society, or at least a centre from which literature, approved of by the society, could be distributed. Thus far three educational pamphlets have been issued, and already thousand of copies of them have been distributed. They are entitled (1) *The Relation of Social Diseases with Marriage and Their Prophylaxis*, (2) *Educational Pamphlet for Teachers*, (3) *The Young Man's Problem*.<sup>8</sup>

I think the time has now come for the issuing of an educational pamphlet entitled *The Young Woman's Problem*. Perhaps one of our distinguished lady members of the society will undertake this task. I am willing to confess that the issuing of

<sup>5</sup>A bill to do away with some of the worst evils of the dancing academies, dancing schools, and dance halls has been introduced by Mr. Graubard and has already passed the assembly.

<sup>6</sup>*The Control of Syphilis and Venereal Diseases. The Society of Sanitary and Moral Prophylaxis: Its Objects and Aims, Social Disease and Marriage. Results of the Work Accomplished by the American Society of Sanitary and Moral Prophylaxis.*

<sup>7</sup>Such societies have been founded or are in progress of formation in the following cities: Baltimore, Md.; Boston, Mass.; Brooklyn, N. Y.; Chicago, Ill.; Denver, Col.; Detroit, Mich.; Jacksonville, Fla.; Philadelphia, Pa., and the City of Mexico.

<sup>8</sup>This literature can be obtained by applying to our secretary, Dr. Edw. L. Keyes, Jr., 109 East Thirty-fourth street, at the following rates:

(1) 72 pp., 45 cents; 5 copies \$1; 25 copies \$5.  
(2) 10 cents; 50 copies \$3; 100 copies \$5.  
(3) 32 pp., 10 cents; 50 copies \$3; 100 copies \$5.

such a pamphlet has already been under consideration, but we who belong to the strong and fearless sex have not yet had the courage to undertake it. It is strange that nearly all of us hesitate to write or speak plainly on one of the most vital subjects which concern the human race. There exists an excellent article by Dr. Woods Hutchinson on the subject of *The Economics of Prostitution*.<sup>1</sup> I have read and reread it, but no passage has impressed me so much as the following, which may well serve as a guide to the author of the educational pamphlet to be entitled *The Young Woman's Problem*:

The freedom of intelligent, refined conversation upon sexual subjects ought to be broadened; it should no longer be considered indecent to speak plainly. Most of the flavor of obscenity which hangs about the discussion of sexual matters is due to this very restriction. No excuse or danger should be left for boys and girls on the grounds of ignorance of this important function. In other words, intelligence, altruism, true refinement, should be promoted by every possible means, and Nature will continue to assist us by emphatically discouraging their opposites.

Besides the educational pamphlets which should be carefully distributed, nothing is so valuable as the carefully prepared popular lecture. But it is not always easy to speak the language of science in the language of the people, and to lecture on the subject under consideration with the necessary force and clearness will require much tact and skill. But I have faith that the executive committee of our society will choose the right men and women for that purpose. When they are chosen I trust that our supervisor of lectures, that great popular educator, Professor Henry M. Leipziger, will realize the importance of educating the adult population as well as the younger generation regarding this great problem, and will inaugurate a series of popular lectures on the prevention of this ill, as he has done for the prevention of other ills.

I cannot leave the subject of education without saying a word as to what can be done in the line of educating the school child in regard to the sex problem. We have had in this society from time to time men and women who have told us that it is quite feasible to teach the children, according to their age and understanding, what they should know of this. At one of our recent meetings we had the privilege to listen to Mr. Curtis, the superintendent of the Curtis School, who has made it a practice to educate children under his charge in all that is necessary and useful to have them think and act rightly in regard to this vital problem. From the interesting literature he was good enough to send me I will quote only a few sentences:

There is nothing in the world half so powerful as right knowledge to suppress impurity of thought, word, and deed. Whoever is responsible for the training of children and is unwilling to instruct them about the meaning and the sacred relations of sex takes an untenable position. He practically confesses that ignorance is better than knowledge. The child with its healthy instincts unconsciously repudiates this assumption, and will forever continue to do so. The whole subject, rightly studied, is in itself so essentially beautiful and so ennobling in all its relations to character that one cannot untold it step by step to children without finding in it new impulse to delicacy of thought and to elevation of purpose. . . . It was recently written that it is a cardinal sin to allow a son to reach manhood years without knowing all that pertains to good,

pure, refined womanhood—all that chastity, wifehood and motherhood means to a woman.

But we may say that it is also a cardinal sin to allow a daughter to grow up and blossom into womanhood without knowing all that she should know as a woman, as a prospective wife, and a future mother. The home is the ideal source of such information, but as yet few homes give it. It is left for the schools that dare to do so to instruct children on these vital themes. Neither must the teacher be satisfied with this partial performance of his duty; he must reach out beyond the child, and touch public sentiment in order to elevate it.

Those who have carefully studied the many causes which make girls with a fair education and a good home training enter the life of prostitution will know what a large contingent comes from the workers employed by manufacturers of women's, men's, and children's garments, in factories or tenements, and that perhaps an equally large number come from the underpaid girls working as clerks or saleswomen. It is often said that their great love for finery leads them to ruin. This may be so at times, but surely this is not the most frequent cause. For the girl without a home it is hard to live on \$4 a week. With her it is want for bread and not finery which drives her to despair.

This is not the place to discuss why women should be paid so much less for their work than men. A few weeks ago I saw, at the Congestion Exhibition, various articles manufactured by the children, young women and mothers of the tenements, as for example: Infants' dresses, 6 cents a dozen; rate of earning, 3 cents an hour, or 42 cents in 14 hours. Glove finishing, 6 cents to 15 cents a dozen pairs; 3 persons work for 60 cents a day. Artificial flowers, \$1.25 a gross sprays; average, 3 persons one-half gross a day. Small hot water bottles, 1 cent a dozen; 20 an hour by expert. Men's neckwear, 55 cents a dozen for lining and hand sewing; average, \$4 per week.

You all know—and if you do not know you ought to know—of the work of the Consumers' League of the City of New York, which should have its counterpart in every city of this fair land. You should be familiar with what this league has termed a "standard of a fair house." It means, in substance, equal pay for work of equal value, irrespective of sex, reasonably short hours, and sufficient attention to the physical and moral comfort of the women employed.

The Consumers' League publishes a white list which the governing board recommends to its members and to all others interested in the welfare of working women and girls. In this white list all the retail houses are mentioned which deal justly by their employees and approach nearest to the standard of the league.

A little propaganda among men, or better yet, for the stronger sex to join as active cooperators with the ladies of the Consumers' League against the sweatshop system would also seem to me timely.

I cannot leave this subject without also saying a word to all the manufacturers and heads of department stores and other large establishments, many of whom are even philanthropically inclined. Let all who have not yet complied with the standard of

<sup>1</sup> *International Medical-Surgical Bulletin*, August, 1907, p. 384.

the "fair house" remember one thing: It is a greater philanthropy to pay the girls in their employ living wages while they are still among the living, so that the temptation to err will be removed, and to have an active interest in their employees' physical and moral welfare, than to leave millions in their last will and testament to cathedrals, churches, hospitals, and similar charities.

We must acknowledge that much has been done of late in various States to curtail the curse of sweatshop and child labor, but there is much more to do. It would seem that all regulation of child labor, woman and sweatshop labor in general in tenements is futile, and that prohibition, direct or indirect, of work in living rooms is the only rational solution of the problem which is responsible for so much disease, misery, and physical and moral deterioration of the laboring population, and particularly of women and children.

The young girls who fall victims to the social ill do not, however, come only from the cities. A large contingent of them comes from the smaller towns and villages. We all know that the attractions of city life have led many a young girl and also young man to leave the healthful home surroundings for the complex and often dangerous city life. These young people, tired of the humdrum existence in the village, flee to the city, thinking that there they will find joy and pleasure and much less work than they are obliged to do at home. If the young man fails to succeed, has indulged in pleasures in which he would not dare to indulge at home, or even if he has done greater wrong, he may nevertheless return home, be again respected and honored, and marry a good, pure young woman.

How different with the girl! She may have loved but once, though not wisely, and upon her are suddenly thrust the responsibilities of motherhood, and in this condition she may be alone in a strange city, without friends or means. She does not dare to return to her home. Though she may be innocent in the eyes of a higher judge, she knows that human society at large will condemn her, and often her very family disown her. For the sake of being able to support her child, whom she loves as all mothers do, the girl thus abandoned finds it hard to find honorable employment, and thus not infrequently enters the ranks of what society is pleased to term "fallen women." More of such work as is done by the New York State Aid Charity Organization, providing homes for mother and child and employment for the former, is urgently needed in our own and other American communities.

Alas! woman herself not infrequently joins in the denunciation of her unfortunate sister, and helps to stamp the mark of an outcast upon her. A little more humanity, a little more sisterly love, a little more compassion is needed here. Let woman be more womanly toward her sister who may have fallen, but nine times out of ten through no fault of her own. A helping hand stretched out to the unfortunate child-mother will often prevent her from becoming a prostitute.

What remedy have I to offer to combat the unfortunate tendency of young people in villages and small towns to migrate to large cities with an uncertain prospect of being able to make an honest living?

Practical philanthropy cannot do the work alone here. If we wish to stem the tide of migration from village to city, and perhaps at the same time reverse the tendency as far as is in our power, thus helping to relieve the congestion and tenement evils already referred to, both practical philanthropy and practical statesmanship must come to our aid. By judicious and wise laws farming should be made more profitable, and thus offer more attractions to the rising generations than it has been doing during the last few decades.

Philanthropists should aid the statesmen by endowing institutions for instruction in scientific and profitable agriculture, and also by providing healthful amusements, good libraries, and other educational institutions in country districts, thus making living in the country more interesting and attractive to the young people.

A large contingent of the unfortunate women in the larger cities, about which we are speaking, is sent there by importation from the interior of the country and from abroad. All social workers are familiar with what is known as the "white slave traffic." Our laws seem to be too elastic or their enforcement too lax to make any impression on this disgrace to civilization. It was recently my privilege to listen to an address on *The Protective Work of the Travelers' Aid Association* by Miss Grace Dodge. If there is any movement which needs strengthening, co-operation, and support, it is this. One of the most important features of the noble work of those actively engaged in this movement is to meet the lonely woman traveler on her arrival in a great city and protect her from falling into the hands of the persons who may have enticed her to come to the city under promise of lucrative employment, but whose interest is to make of the unfortunate victim a slave.

We come now to that part of our subject which I believe is the most difficult of all to discuss, namely, treatment. How shall we deal with prostitution as it exists to-day, with its widespread ill, known as venereal disease? You all know that neither prostitution nor its concomitant physical diseases are a product of modern times. Herodotus (484-424 B. C.) tells us of prostitution in ancient Babylon, and venereal disease seems to be almost as old. Emancipation of woman, which has been slow but sure, has, in my humble opinion, certainly done something in improving conditions, and when we compare the history of prostitution of old with that of to-day we can still say it is better now. Nevertheless, it exists, and whether it still flourishes because of man's passion, or because of our social fabric, which only permits too few and too late marriages, or because of injustice of man to woman, or because of lack of the divine in all of us, or because of all these causes combined, I do not pretend to be able to say.

I have said in the beginning of my address that I look upon the situation as a disease, which, after everything has been done in the line of prevention, must be treated. This is the attitude which every physician takes when he is in the presence of illness. In my humble opinion, the disease with which we are confronted at this time can be treated in the present state of civilization by three methods only, namely, first, by repression; secondly, by giving to all

those who are diseased the best, most thorough, and scientific medical treatment; thirdly, by offering to all those who wish to leave the ranks of prostitution shelter, protection, and work.

Let me, in conclusion, dwell for a few moments on each of these three therapeutic topics. In reference to the first, let me defend my position, which is for repression and not for oppression, and repeat what I have said once before on the occasion of addressing the Society of Medical Jurisprudence: "I doubt the wisdom of our lawmakers, city fathers, and reformers in perpetually hounding the unfortunate prostitute. These women are driven away from one part of the city only to turn up in another, and, instead of confining the evil to one section, it is spread all over. I have the strongest doubts that the social ill as such can be suppressed in a city like New York by no matter how strict a police regulation. It has been said by authorities who have studied this subject very thoroughly that there is always a natural tendency to segregation, just as there is a tendency to segregate among other trades. It certainly would seem that if some kind of segregation could be accomplished by passive or even by active measures, so as to limit this social ill to some portion of our city which could be properly controlled by an efficient police, it would stop the concomitant thievery and robbery and greatly diminish that still greater crime of having men live on the shame of women. Remove by sensible and just laws the necessity of bribe giving, and the bribe giver will cease to exist. I do not like this perpetual cry of some against a corrupt police, an inefficient judiciary, etc., etc.

"Let us make laws that can be enforced. Remove the ridiculous character of some of the laws, and you will find the vast majority of our policemen true guardians of the peace and willing to perform their duty, and our judiciary you will find as spotless as any."

I have mentioned as the second part of my program of dealing with the social ill the most thorough, scientific medical treatment. There is not a physician in New York, from our distinguished president down to the young graduate serving in a public dispensary, who will not tell you that, while venereal disease must be considered one of the most prevalent of all infectious, contagious, and communicable diseases, for its treatment there is an almost total lack of facilities and system in this as well as in most cities of the United States. From statistics gathered by Dr. Armstrong and published by Dr. Mewborn in a paper read before this society, the lamentable condition has only been too plainly demonstrated. The City Hospital and the Metropolitan Hospital are the only two institutions in this great metropolis which have beds for the treatment of venereal diseases. The combined capacity for this purpose consists of one hundred and twenty beds for male and thirty-three beds for female patients. The evident need of many, many more hospital facilities to treat this class of patients must be evident even to laymen, especially when the physician tells them that hundreds and hundreds of cases of people, and particularly women of the unfortunate class under consideration, are now walking the streets of New York knowingly or unknowingly spreading the

disease broadcast and causing untold misery and suffering. If hospital facilities would be provided for them I am quite sure a goodly number would avail themselves of the opportunity to be cured. There is, however, one condition on which I would insist in providing such hospital facilities. There should be no special hospital, but there should be special pavilions or special wards attached to a general hospital. If we wish to induce the afflicted to go there we must avoid the stigma which would attach itself to the name of a special venereal hospital. It has been said by advocates of licensing and regulation of prostitution that more cases would be treated and cured under such a system. I have no evidence that this statement is correct, but, if statistics are reliable, the disease under consideration would seem as frequent in some countries where there is regulation as where there is none. But it is difficult to see why, among women suffering from venereal disease, a large number would not gladly avail themselves of the opportunity to be examined, treated, and cured. To this end our dispensaries for the treatment of venereal diseases should be multiplied and they should be so managed that any woman or man, fearing to be infected, could be assured of humane consideration and scientific and thorough treatment. Who will dare to deny that much sorrow and much suffering would thereby be spared to the community at large?

Would it not be wise to offer to all these unfortunates an opportunity to at least regain their physical health, and thus stop at the same time a source of infection to others? If it was only to save the lives of the innocent and prevent the blindness of thousands of little children by saving them from gonococcal infection, it would be a vast economy to a community to treat as many of the infected adults as possible.

I come finally to the third and last of the remedial agents I have to offer. It is a shelter to receive all those who voluntarily wish to leave the life of prostitution and who fear to return home or are not able to make an honest living, or, worse yet, fear that individual who does not deserve the name of man for having lived on the shame of woman.

All those who have studied the problem without bias and with only the view to help where help is needed will realize the need of such an institution. You may be pleased to learn that, owing to the inspiration and indefatigable energy of Miss Maude E. Miner, probation officer of the city magistrates' courts, such a home has been started already on a small scale. Most gratifying to all those interested in this work was the endorsement of the city magistrates. At a recent meeting they unanimously voted their approval of the establishment of a home for girls released from court on probation. Funds are coming gradually, and those of us interested are full of hope that ere long we may be able to put it on a sound financial basis, and make this home large enough to receive girls whom the probation officers from all over the city courts may choose to bring to it.

It was my privilege recently to spend the hours from 9 p. m. to 3 a. m. at the side of the city magistrates' court of the night court. I had not been converted that night to the need of such an institution, the two

incidents related to me by Miss Miner would certainly have convinced me of the need of shelters and homes for the unfortunate women who are seeking to be freed from the life of shame. Let us use Miss Miner's own words:

A young German girl was arrested recently for soliciting on the streets and was placed in my care. Two months before she had been working regularly and living a good, honest life. With tears and sobs she told me her sad story—how she had met the man who lured her from her work, how she had gone to live with him, and then how he had forced her, four weeks later, to go on the streets and support him by her immoral living. She declared that she wanted to give up the wretched life and was willing to go with me to any home to which I might take her. It was with great difficulty that I succeeded in finding a place for her.

Another girl was pregnant, and had been forced to solicit because she had not a cent for food, had no home. The institutions at whose doors I knocked refused to admit her, so that my only solution was to take her with me to my home.

It is Miss Miner's ambition, and it should be ours, to have many such homes and in the various cities of the United States, and thus by interchange facilitate the reentrance into proper and honest spheres of life any girl who voluntarily leaves the ranks of prostitution.

I have endeavored in this feeble effort to point out to you a few of the most urgent things which must be done if we wish to deal with this all important problem intelligently. We must approach the subject of prevention and treatment of this social evil with no sentimentality, but practically, prepared even to be disappointed now and then, yet remain charitable and continue the work without fear and on the principles of the broadest humanity.

To those who are afraid to deal with the subject or think themselves above it, to those who fear to touch it because it is too dark and too sad, as well as to those who are willing to help their unfortunate sisters, let the words of the Great Physician be their inspiration and reward: "Inasmuch as ye have done it unto one of the least of these ye have done it unto me."

16 WEST NINETY-FIFTH STREET.

## THE PSYCHIC PHENOMENA OF INTESTINAL TOXÆMIAS AND THEIR TREATMENT.\*

By J. CARLISLE DE VRIES, M. D.,  
New York.

The treatment of indigestion is of peculiar interest to the members of the medical profession, especially in view of the fact that the profession is divided as to the advocacy of surgical intervention in these cases. Operative procedure is not as successful in producing the ultimate end as sound, common sense scientifically applied.

I have been placed for the past six months in an admirable position to study this class of cases, during which time I have been in daily attendance upon at least forty to fifty cases of some form of indigestion either primarily or as an accompanying symptom of some other disease.

I will cite at length one or two illustrative cases of this character. The first one is that of a very learned reverend gentleman, whose history I append

in his own language; the next is that of a very prominent physician, at the present time in practice in Utica.

CASE I: Rev. W. H. O., age thirty-four.—"The first attack of intestinal toxæmia from which I suffered occurred about the middle of July in the year 1901. I had eaten heartily of crab *farc*i one day, and awoke the next morning suffering from a most violent vertigo, which was followed by diarrhoea and nausea which continued almost incessantly for a period of nearly one half hour and ended with the emission of bile of a dark, green color. As this vertigo was typical of all the attacks which followed, I will describe it in some detail. It was objective, and the things around me—tables, chairs, pictures, and pattern on the wall paper, etc.—rotated with extreme rapidity in circles with a radius of about eighteen inches, in vertical planes. For several days after this attack I was exceedingly unsteady on my feet, and my head was heavy, although at this time I did not experience that subsequent trouble with my vision which I had at a later period following these attacks, and by which things appeared to me blurred and indistinct, and I saw as if through a curtain of unreality.

"My second attack occurred in February of 1905 after eating a club sandwich with rhine wine and soda. This attack was comparatively light and of short duration and with only slightly pronounced after effects. I did not suffer again from the trouble until the 15th of June, 1906. During the winter of 1906 I had been extremely busy and also very nervous, suffering in addition to nervous anxiety with a difficulty with my right ear, which has since been pronounced to have been in no way an attack of Ménière's disease. In April of 1906 I left New York and became rector of a parish in one of the suburbs of the metropolis. Here I was not only extremely busy, but had many things of importance and difficulty to worry and annoy me. I ate quite inordinately of everything that was set before me; with particular heartiness of strawberries and things made of chocolate. I recollect, however, that I felt extremely well on Sunday, the 17th of June. Early next morning I awoke with a slight attack of vertigo such as I had had in 1901 and 1905. This soon passed off, and I fell into a profound sleep such as in many cases followed later attacks. I breakfasted that morning as usual, and suffered a slight return of the vertigo after breakfast. I went to New York, however, where I had some matters of pressing business to attend to. All went well until I was within a few blocks of the Grand Central Station, where I was seized with a most violent attack of vertigo and fell in the street as if I had been shot. A policeman with great kindness and apparently sincere attention took me to a club of which I was a member, in the neighborhood. Here I was seized with nausea and diarrhoea, and experienced a most profuse perspiration which struck completely through to the back of my coat. I received medical attendance, and was able to return to my home that night. The following morning I again had a slight attack of vertigo, and following that day for nearly two weeks I was extremely ill, having many and still more violent attacks of the vertigo, a pulse of 46 for several days and temperature considerably subnormal. It was almost impossible for me to keep any food upon my stomach, and I began to be attacked with very pronounced nervous symptoms. Those of my family who were with me said that I spoke and acted in a very peculiar manner. The slightest unexpected movement in the room or the sudden entrance of a person into the room caused me to start as if I had heard the report of a revolver. In course of time, however, I was able to be about, and then began a sensation which was hardest of all for me to bear, and which has taken the greatest while, nearly a year, for me to overcome. This sensation I should describe as being similar to that experienced when skating upon rotten ice or when on board a ship which was rolling considerably. I cannot, however, tell if it was objective or subjective. For many weeks it was with difficulty that I could walk straight upon the sidewalk, and I felt under the necessity of dodging all the lampposts and telegraph poles I saw.

The shock of my fall in the street was such that for many months I was unable to go about unaccompanied without the strongest sensation of fear.

By September of 1906 I seemed to be quite well, and by the 1st of October appeared to be enjoying that good health which had been practically unbroken for the pre-

\*Read before the Tri Professional Medical Society of New York, January 10, 1908.

vious seventeen years. On the night of October 10th, however, I ate heartily of fried pan-fish, and about one half hour after supper I had a slight attack of vertigo, which was followed by a pronounced renewal of the dreaded unsteadiness. All of this wrought upon me so that by the middle of November I seemed to be a complete nervous and physical wreck, and was obliged to withdraw from my work. I again experienced attacks of vertigo followed by the usual conditions; my temperature reached a lower point than in any of the previous attacks, and my pulse was still slower; the action of my heart seemed to be extremely irregular, and I could not concentrate my thoughts nor use my mind without experiencing sensations of pressure upon my head and temples and rushes of blood to my face. My nervous condition was deplorable; I could hardly speak or think, and yet, curiously enough, I never once, either then, before, or since, suffered in the smallest degree from insomnia. For several weeks I lay under a most awful calamity to occur, and can only describe this sensation by saying that it was such as I would imagine one to experience who saw a dear friend advance unconsciously in front of an express train going at full speed, and was the while utterly unable to prevent the approaching tragedy.

About the middle of January, 1907, I began to improve, and my progress was most surprisingly rapid until March, when I very foolishly ate heartily of some chocolate fudge, and next morning woke up with the vertigo. I was very ill for nearly two weeks and suffered from my old symptoms. Yet it is interesting to note that while these attacks of toxæmia were far less severe than those I had previously experienced, the nervous after effects were, if possible, even more violent.

To make a long story short, it was absolutely necessary for me to withdraw from the presence of my church and church work. I went to England, hoping that quiet and change would benefit me, but the result was quite the reverse. I returned to America in July, 1907, and while on the steamer again suffered an attack of toxæmia, less violent, quite truly, than I had had before, but accompanied by the same distressing symptoms.

"I am not writing at all for the sake of advertisement, but I believe that the treatment which I have undergone has been successful in relieving me of the dreaded toxæmia with the after effects and in rebuilding a physical condition greatly depleted, thereby enabling the weakened and poisoned ganglia of my sympathetic nervous system to resume their work, which is so necessary for the maintenance of the human organism."

CASE II: Dr. E. V. D. G., age forty-one.—"It is almost impossible for me to say positively exactly when my peculiar physical ailment originated. As a boy I was of a rather stocky build, rugged and hearty. I had the usual diseases of childhood; but, to the best of my recollection, I had no serious disease, with the exception of a light attack of pneumonia, until I was about seventeen. During that summer I was taken ill with what the medical men in attendance called a 'spell of fever.' This is not a very definite diagnosis from a medical standpoint, but it is the best I can give for the reason that this is all the said medical men told my family. All I remember of this illness is that I had been feeling badly for some time, and finally had to give up. I was in bed for about a month, and it was another month, and so I was out of the house. Severe frontal headaches, acute sensitiveness to light and noise, fevers, and delirium followed by extreme and prolonged lassitude, are all the symptoms which I now recall, and these are none of our family at the present writing at hand to refresh my memory. I do remember, however, that on a few occasions when I was quite a child I suffered from what my elders called 'fainting spells.' These spells never lasted long and to the best of my recollection I never actually lost consciousness."

"I did not attain my full growth until my twenty-first year. My height is now six feet and three inches, and I am about as slender as I am tall. Previous to twenty-one I never lost my appetite. From that age I dropped the scale of life."

While these facts may not be of great importance, I mention them, as it has occurred to me that perhaps my rather rapid growth between the ages of sixteen and twenty-one may have undermined my general physical condition, particularly as, during those years, instead of con-

tinuing my studies I was clerking in a business which required of the employees of its wholesale department much hard physical labor and heavy lifting.

"At the age of twenty-one, I commenced the study of medicine. There was no provision for the feeding or lodging of the students at that time at the institution of learning which it was my privilege to attend, so that the men were obliged to obtain lodgings where they could find them and eat when and where their means would allow them."

"I had a room near the college, but I obtained my meals at first one place and then another, frequently changing, for as we all know, the menu of even the best boarding house soon falls upon one, and student boarding houses are not particularly noted for being of the highest class. Perhaps the irregular life I led during this time had its influence upon my alimentary tract."

"With these preliminary statements, I will now endeavor to give an account of the (to say the least) unpleasant attacks to which I have been subjected for several years past, and of my present physical condition."

"It was in the spring of the year 1889 that my attention was first very forcibly called to my state of health. The spring term of the college year had closed, and I was visiting a relative who lived in the same city in which the college was located. There was to be a dinner of my class or fraternity. I had dressed preparatory to going to the place of meeting, and was about leaving this relative's home when, without warning, a peculiar feeling came over me. I cannot accurately describe this feeling even now after the lapse of all these years, and after having gone through many similar attacks of greater or less severity, few of them greater, almost all of them less. Suffice it to say that the very first sensation is one of dread, not fear, but dread of something. Exactly what that something is I never have been able to discover. Quickly following this feeling is a condition in which my brain seems to be groping around in semidarkness in a vain endeavor to grasp some very faintly defined thought which constantly eludes the pursuit. My pulse becomes rapid and irregular, and my heart seems to come up as a lump in my throat and choke me. During this period I am conscious of what is going on around me, although I feel weak, my hearing is dulled, my sight is dim, and it is only by the greatest effort that I can speak, and then my speech is thick and jumbled. My instinct is to lie down perfectly flat, loosen all my clothing, especially about the chest and throat. I should also say that my breathing is somewhat difficult."

"Now, if I can get some stimulant at the proper moment, right at the start, the attack will almost invariably end at this stage, in fact it will be cut short before it is necessary for me to give up and lie down. I have tried aromatic ammonia, whiskey, etc., but whiskey taken straight and followed by a little water seems to do the work best."

"If I had followed the treatment which I adopted (I might say instinctively) upon the onset of my first attack, that is, had I laid down, or even kept quiet for a while, probably what occurred would not have happened. But I was new to this sort of trouble, I was young, and I was anxious to get to that dinner and enjoy myself; so as soon as I felt somewhat better I left the house. My destination was some distance away. I was already late for my appointment, and my natural course of action would be to board a car, but I did not do so, why, I cannot say, except that I did not feel quite right, and I shrank from coming into close contact with my fellow-creatures. Right here I ought to say that this feeling is and always has been present at these times. I prefer being instantly alone to having any strangers with me. Later on, after some memory of my really bad attacks and of the nature of these attacks, I did not object to their presence as much, although even while I was suffering I have always sympathized with their feelings (those felt for them), for I have realized that it must be the same feeling, especially in a form as it must be at those times to witness another suffer, and even to die in this life."

"I had one well-remembered time that I got into these black fits on a train before the passenger agent had returned with my ticket, and I was compelled to leave. There are other times when I have been alone at home, and I have found myself in a room by myself, and I have been completely alone. My own feelings are all that I have, and I am conscious of the most mysterious and unaccountable things about myself, yet I could not dream of them at the time."

"Seems now appalling, I went out to the street to find a doctor, but the doctor I remembered until my illness

later. It seems that just as I reached the car I lurched forward and fell, striking my head upon the car step and cutting a gash in my forehead. A policeman was summoned, who called an ambulance, and I was taken to a hospital. In some ways it was fortunate for me that I had received the cut, as otherwise I doubtless would have been treated as a plain drunk, for, as I afterward learned, the odor of whiskey was very plain upon my breath.

"It was some hours later that I came to myself, and then it was to find several physicians and nurses standing around my bed. I was in evening dress and there was nothing upon my person by which to identify me. The doctor commenced to question me, but I was still dazed and found speech very difficult, and it was some time before I was able to give an account of myself. By the time I was able to do so I had recovered my strength to some degree, and I was put in a carriage and sent home. The family were naturally very much frightened; a physician was sent for at once, who gave me some sedative and left. The next day he and two others examined and questioned me, held a consultation, and decided that it was a case of brain fag from overwork, and advised that I should get out in the wild and live an open air life for some months. Accordingly, I was sent into the mountains of the south, where just at this time an attempt was being made to open up some of the iron and manganese mines which had been shut down since the civil war. In this region I remained for about fifteen months, living a rugged out of door life—in short, roughing it. During this time I grew hearty and apparently well, and yet at intervals of varying lengths I would suffer from these peculiar attacks, but not nearly so frequently the latter part of the time as at first.

"This brings me to the autumn of 1890, at which time I returned north and again resumed my studies, being graduated in the class of '92.

"Winning my appointment on the house staff of a certain hospital, I served my term and started on the active practice of my profession. To me it seemed a rather strange fact that although during my last two years of college I suffered from several severe attacks, during the eighteen months of my hospital service I had only a few attacks, and none of these severe. Not once were my duties interfered with, and yet, as we all know, the life of a house physician or surgeon is neither an easy nor a regular one. Nor, for a while after I started in private practice was I much troubled, but as my work and responsibilities increased, especially the night work, I found that the curse of my life was again being visited upon me, and the attacks grew more frequent and more severe.

"In May, 1903, I suffered a serious accident, being run over by a cab and rendered unconscious. I was home five weeks, the first three of which are a total blank. My nights were the worst part of the twenty-four hours, as then I was particularly restless and irritable. I had received a blow on my head and the fifth and sixth ribs on my left side were fractured; I was a year getting well, and during this time I was out of the city at a summer resort, and did not even have the slightest suggestion of an attack, and the following winter but few, and these of a mild character, but shortly after again taking up practice their frequency and severity increased, and I became more and more nervous, my appetite became poorer and poorer, and my digestion even worse, with much flatulency. I have never been a great sleeper, but insomnia became a very marked symptom, and I would go for weeks with not more than from three to five hours' sleep at night and very frequently would pass the night with none at all. I found it difficult to concentrate my mind, and seemed to be unable to grasp the meaning of what I read. My memory became so poor that often I could not even recall events of importance after the lapse of a short period of time.

"Being unconscious during an attack, I cannot describe the symptoms and my actions during one, except that I frequently vomit a great deal of bile and afterwards pass much mure from the bowels. An intensely severe headache invariably follows and lasts hours and sometimes days. Pain in the abdomen, especially in the gastrohepatic region, is another symptom always present, and the abdominal muscles become rigid. If there has been a convulsion all the voluntary muscles are tense and some afterward, and my right hand is found placed over the liver."

What causes the awful depression, the dread, fear? Is it the undigested food that remains in the intes-

tinal canal, is it the toxins produced thereby, or is it the lack of entire absence of peristalsis? I have seen cases with perfect peristalsis and normal bowel movements, and yet these same morbid symptoms persist.

Take the suicide statistics. They either kill themselves because of financial reverses, broken hearts, or other causes; yet the physician in attendance, it questioned, will say that almost the last symptom of the patient was constipation or indigestion.

I must now call your attention to a case in point; the main symptom in his history was chronic constipation and indigestion. He said that he had not had a normal bowel movement in twenty years, thought he never would get well, had delusions, was inordinately depressed, in constant fear of a twisted gut, and thought the best way out of his misery was suicide. It seemed his one thought.

Another case is that of a prominent lawyer of Rochester, who was rapidly going insane, as he termed it, because his bowels would not move, because he could not digest his food, because his intestines were dilated with gas during the night, and at this time his morbidity was much increased. He passed out of my hands, and has since made away with himself.

Another case, the wife of a former State treasurer of Pennsylvania, who, when her digestion was perfect and her bowels regular, complained of nothing, notwithstanding the fact that she had Bright's disease and arteriosclerosis, and yet when she became constipated in the slightest degree, or when any part of her meal did not agree with her, her depression was absolute, suicide being her only topic of conversation.

The great indication in the treatment of this awful condition is to remove the cause.

Nervous anorexia, or a complete absence of the sensation of hunger, associated with loss of appetite, is a very difficult condition to combat. This symptom of neurosis usually follows some great depression, family troubles, or some other cause. The onset of the symptoms is gradual, the patient first discarding the heavier articles of food; later almost every form is refused. The diagnosis is not difficult if one sees the patient at the very commencement of the disturbance. On the other hand, if you see the patient after emaciation has become marked and no history can be obtained, diagnosis is obscure. It may resemble tuberculosis, and the symptoms, no appetite, anemia, pallor, asthenia, may also resemble cancer. However, loss of appetite from organic disease of the stomach, whether due to catarrh or cancer, is almost always accompanied by fear and dread. In nervous anorexia the patient seems to be totally indifferent to this as well as other changes in his environment. In this condition food should be given at frequent intervals and should be varied. Some one of the bitter tonics given a half hour before meals is helpful. Later, after emaciation has resulted and the condition is chronic, residence at a health resort for several weeks is necessary. Depression of spirits is very marked. The high frequency current, and occasional forced feeding and hydrotherapy consisting of a salt rub, a needle bath, Charcot douche, an electrothermal bath, with an occasional massage, usually effects a cure in these cases.

The term *neurasthenia gastrica*, or nervous dyspepsia, implies those vague, incompletely defined disturbances which occur during the digestive act. The patients show no demonstrable change in the stomach. Many and varied clinical symptoms with no organic lesions are present in this disease. This unbalanced state may follow debilitating or chronic diseases, sexual excesses, abnormal conditions of the genitourinary organs, great and sudden nervous shocks and breakdowns.

The patient experiences discomfort after food, a sensation of fullness, slight burning, belching, drowsiness, and fullness in the forehead. These symptoms often continue through the period of digestion and are followed by sensations of dizziness and weakness. In many cases the patient will be uncomfortable at all times, whether the stomach is empty or full. The intestines are not free from apparent disturbance. The patient says that he feels that his abdomen is filled with gas, and he is usually constipated. Nutrition may become involved, and the patient loses weight. We are not justified in diagnosing nervous dyspepsia if we find food in the stomach six hours after a dinner consisting of mixed foods. The absence of blood is a strong point favoring the existence of nervous dyspepsia.

Pain usually disappears on pressure when due to nervous dyspepsia, and is increased if due to ulcer. If nervous dyspepsia is associated with neurasthenia we find typical tender spots.

Where the diagnosis is not certain, the patient should be subjected to the rest cure, as the best results are brought about by this course. Cold baths, shower baths, and occasionally a hot brine sponge and the vibrator are very efficient.

Ichthylol in divided doses to be continued for an indefinite period, or ichthalbin (ichthylol albuminate) in combination with one of the valerianates is one of the best mediums for the absolute relief of the neurasthenic type of intestinal derangement.

How many of these cases report that they are feeling fine, that their bowel evacuation was abnormally large and satisfactory, and that the relief they experienced was perfect, and then within twenty-four hours they experienced a return of all the old symptoms. Does not the toxemia stimulate before it prostrates? I have found this to be the case in many patients. I have also found a very rapid pulse in one attack and a slow pulse in another in the same patient, all due to a variation in gas pressure on the pneumogastric nerve.

# WHO ORIGINATED THE METHOD OF RAPID PARAFFIN IMBEDDING? A REPLY TO DR. POND.

BY ARTHUR STEIN, M. D.,  
New York.

On November 19, 1907, there appeared in this journal among the original articles one by A. Pond entitled *Improved Rapid Method of Imbedding Histopathological Specimens in Paraffin*. Dr. Pond describes a method by means of which it is possible to make paraffin sections of fresh patho-

logical specimens in one and a half hours. As he mentions no literature on the subject it would appear he was the originator of the method. Even if he developed it independently of those who worked along these lines, it would have been no more than just to refer to their publications, especially as these date back several years. The latter fact in itself goes to show that the method described by Pond is not a "new or improved one." Moreover, it would have been an easy matter to obtain information of this kind in Schmorl's book, which is universally acknowledged as one of the best on the subject.

As I have been using the rapid method of preparing paraffin sections for several years, I take the liberty of summarizing what I wrote concerning it in 1903.<sup>1</sup> At that time I stated that I had been using the method for one and a half years and that I followed the verbal directions of my teacher, Lubarsch:

The fresh specimen is first fixed in a 10 per cent. formalin solution for about five minutes, when it is put into 95 per cent. alcohol for another five minutes, and then transferred to absolute alcohol in which it remains ten minutes, the absolute alcohol being renewed once. After having been in absolute alcohol it is immersed in perfectly clear aniline oil until it has become entirely transparent, a process taking on an average from fifteen to twenty minutes. From the oil the specimen is brought into xylol, in which it remains until the xylol no longer becomes discolored yellow (this takes about fifteen minutes if the specimen is small). Finally it is placed in melted paraffin for from ten to thirty minutes at a temperature of from 58° C. to 60° C. I wish to emphasize especially that the vessels containing the various fluids are kept in the incubator. In this way the specimen is impregnated much more rapidly than if the fluids were kept at room temperature.

To recapitulate, Lubarsch's method of rapid hardening and rapid imbedding (under which name I described it, and by which name it has since been referred to in medical literature) consists of the following steps: 1, 10 per cent. formalin for about five minutes; 2, 95 per cent. alcohol for about five minutes; 3, absolute alcohol (renewed once), ten minutes; 4, aniline oil until the specimen is entirely transparent, fifteen to twenty minutes; this is to be done in an incubator at 122° F. to 125.6° F.; 5, Xylol, changed two or three times, about fifteen minutes; 6, melted paraffin, from ten to thirty minutes, depending upon the thickness of the specimen. All this is to be done in an incubator at 136.4° F. to 140° F.:

One can readily see that the entire process takes no longer than one and a quarter or one and a half hours, which is less time than Gutman's method (Schmorl's) requires. Of course, it is only suitable for pieces of tissue from one to three millimetres thick (Schmorl), thus being especially adapted for currettings. Nevertheless, tissue from any organ, as already pointed out by Gutman, can be thus imbedded provided the piece has the required thinness.

As regards the durability of the specimens prepared in this way, I can confirm, after several years' more experience, what I stated in 1903 after a trial of only one and a half years. They are durable and in no way inferior to those prepared by the slow imbedding process. My own experi-

<sup>1</sup> *Journal of the American Medical Association*, Chicago, Ill., 1903, p. 1003.  
<sup>2</sup> A. Stein, "The Schmorlizing and Schmorlizing of Histopathological Specimens," *Journal of the American Medical Association*, Chicago, Ill., 1903, p. 1003.

ences have been similar to Schmorl's, who says (*loc. cit.*, page 58):

If we are in a great hurry to examine pathological specimens, i. e., in cases in which tissue is removed for diagnostic purposes, we can use the method of rapid hardening and imbedding, first suggested by Lubarsch, to great advantage. It has recently been recommended by various pathologists and has given excellent results in my own experience.

Let me now quote from Pond's article<sup>3</sup>:

The chief objection heretofore advanced against the use of paraffin as imbedding material was the length of time required to properly harden, dehydrate, and clear the tissue in preparation for the impregnation of paraffin, this process usually requiring from thirty-six to seventy-two hours.

Then follows "Pond's method": 1, 10 per cent. formalin, five to fifteen minutes; 2, 95 per cent. alcohol, five to fifteen minutes; 3, absolute alcohol, not less than ten minutes, and no longer than twenty minutes; 4, aniline oil, ten to twenty-five minutes; all four proceedings to be done in incubator at 122° F.; 5, Xylol, fifteen minutes, changed three times; 6, paraffin, ten to thirty minutes, in incubator at 140° F.

On comparing this "improved method" with Lubarsch's, published by me in 1903, we cannot help but notice a striking similarity not only as regards the order of the separate fluids used, but also with respect to the time which the specimen has to remain in each fluid. With what wonderful accuracy the directions of both correspond! Pond's paper certainly invites one of two criticisms, it either shows a deplorable ignorance of medical literature or it represents an intentional plagiarism.

Any one interested in the different methods of rapid hardening and imbedding may consult the writings of Lubarsch<sup>4</sup> and Pick, as well as a more recent publication by Henke and Zeller.<sup>5</sup>

I have already referred to Schmorl's opinion, which practically confirms Lubarsch's favorable experiences. As far back as 1903 the latter said:

"I can assure you that the specimens prepared in 1889, when I first came to definite conclusions as regards my rapid method, have undergone no change. After using both the rapid and slow method of imbedding for almost fourteen years I cannot detect the slightest difference as regards stain or durability in the sections prepared by the two methods."

I have been told that Weigert himself used Lubarsch's method frequently and successfully. This in itself is sufficient reason to recommend it to Americans. It is especially adopted for pathological laboratories where many specimens have to be examined and where it is important not only to make a rapid microscopical diagnosis, but also to obtain durable sections.

My sole object in writing the foregoing has been to set forth the truth and to give the credit to whom it belongs, namely, to Lubarsch.

## THE ABSTRACTION OF CALCIUM SALTS FROM THE MOTHER'S BLOOD BY THE FŒTUS.

*A Cause of Dental Disease in the Former.*

BY JENNIE G. DRENNAN, M. D., C. M.,  
St. Thomas, Ont., Can.

In an article published in the *New York Medical Journal* of September 28, 1901, I stated that the abstraction of calcium salts from the mother's blood by the fœtus would be a cause of osteomalacia in the former, provided that the diet was poor in such salts, as it would be among the ill fed mothers of the peasant and slum classes; for osteomalacia is a disease the result of a poverty of calcium salts in the blood of the mother, by which her osseous tissues are deprived of this calcifying element. If her diet had been rich in these salts there would be a sufficiency for both mother and fœtus. At the present day, among the better class of patients, one finds a condition analogous to osteomalacia, only on a lesser scale and affecting a tissue which may be artificially replaced by the dentist, viz., the noncalcification or soft condition of the tooth, leading to caries of the dentin and enamel and also to destruction of the pulp. The fœtus requiring calcium salts for the development of its own osseous tissues, abstracts from its mother's blood all the available calcium salts—parasites usually fare better than their hosts—and this leaves none or very little of this material for the mother's organism to replace the wear and tear in her osseous structures, the teeth being one of the first to suffer, probably partly on account of their position, where other deleterious factors are at work—fermentation and putrefaction of particles of food, the presence of secretions which contain germs, and the acid vomit from the stomach coming in contact with them.

If the mother's diet was rich in calcium salts there would be sufficient of this material for both her child and herself; but, as is too often the case, her appetite is extremely capricious, and she does not eat that which she should. At the present day, with life in an apartment and its attending lessened labor, the woman has not the same hearty appetite as had the woman of the forest or the plain; food is not so rich in calcium salts, for much of our prepared vegetable food—cereals—is adulterated, or, at best, so refined as to have removed from it that which is most necessary to the human organism. During pregnancy and lactation the mother's food should be richer in calcium salts than at any other time, because she is then to supply such salts to two organisms—herself and her fœtus or infant, the latter being greedy for such material.

A certain degree of softening or noncalcification in some of the mother's bones at the time of delivery is rather advantageous in aiding in the easy delivery of the fœtus, but faulty calcification of tooth tissue is of no benefit; then, also, a certain degree of noncalcification of bone tissue favors the greater production of blood cells in the marrow of bone, for unstable osseous cells readily break down and are converted into blood cells. This to a certain extent is perfectly physiological, but becomes pathological when the mother's osseous structures

suffer and become incapable of maintaining her in a condition of health. Pregnancy is tending to become a pathological condition.

Caries of the teeth of the mother is due to the fact that they are deprived of their normal amount of calcium salts by the fetus. The calcification of tooth tissue should be normal, but it is not so if the mother's blood is not rich in calcium salts, for the fetus will have its share by depriving the mother; this is then a pathological noncalcification. In the dentine and enamel, as in all other osseous structures, there is constant wear and tear, which must be replaced, and for this replacement calcium salts are needful. By a poor supply of this material the dentine and enamel will lack their normal degree of firmness, and will, in their state of faulty calcification, be easily acted upon by the secretions, fermented and putrefied food, acid diet (of which pregnant women are so fond), and acid vomit. Hard enamel protects the dentine, soft does not. This decay oftener commences from within the tooth—tooth tissue is formed from within out. If the new cells formed in the interior of the tooth for the replacement of worn out cells lack sufficient calcium they break down easily and also tend to approach a lower type of animal cell, one which multiplies and dies more easily and forms putrescent dead matter in the tooth cavity; this causes pain and decay of contiguous tissue—dentin and enamel.

Such a condition may be averted by giving the pregnant woman a diet rich in calcium salts and also by administering to her these same salts in the form of medicine—to-day pregnancy tends to pathological conditions. The fruit diet fad for pregnancy has its drawbacks in that it produces soft bones for mother and child, and the teeth being really appendages, are the first osseous structures to suffer. Children produced on such a diet are prone to late eruption of their teeth and to walk late in infancy. I have just such a case in my mind of a child, seventeen months of age, who has only four teeth and has just walked; otherwise apparently healthy. The mother has poor osseous and muscular development, and lives principally upon a fruit and vegetable diet, not being fond of milk. A mixed diet is necessary for human beings, for they are of the omnivora; from this diet the mother prepares nutriment for the fetus during pregnancy and the infant during lactation. Milk and eggs are both animal products and are rich in osseous forming elements.

Carelessness in the toilet of the mouth, along with the other factors already mentioned, tends to destroy the teeth, but the primary cause is the lack of available calcium salts for her osseous tissues.

Dr. Branth, of New York, in the *New York Medical Journal*, of August 10, 1901, wrote an article entitled Cleft Palate and Its Association with Harelip, in which he mentioned the fact that lionesses fed on flesh containing bones too large for mastication, gave birth to offspring with cleft palates; but, he added, lack of a meat diet and insufficient calcium phosphate in the human mother's case would not cause the same result in her offspring, as the fetus would draw upon her tissues for its calcium salts if there were not a sufficiency by

ingestion. From this statement the question occurred to me—may not this very abstraction from the mother's tissues be the cause of osteomalacia in her? But the question to be first settled is, does the fetus abstract calcium salts from her tissues, or does it do so from her blood and thus appropriate what by rights should go to nourish her osseous structures? This seems to me to be the correct view.

## HYSTERECTOMY OF A FIVE MONTH GRAVID UTERUS FOR CARCINOMA UTERI.

### RECOVERY.

BY WILLIAM H. DUKEMAN, M. D.,  
Los Angeles, Cal.

On March 26, 1907, I was consulted by Mrs. W. H. L., of Yuma, Arizona, age thirty years, and a native of Peru, South America.

She was a lean, wiry person, five feet in height, and weighed ninety pounds. Her general appearance was one of frailty, very anemic, and of an exceedingly nervous temperament. She was the mother of one child, a daughter eleven years old, by her first husband. She had been married to her present husband less than six months. Her menstruation was regular up to five months ago, when she missed for three months. For the past two months she has noticed at frequent intervals, a menstrual discharge of a darker color than formerly, and at times of a foul odor. She complained of a dull burning pain in the vagina which caused her to grow very nervous and restless, causing much insomnia. Her appetite, however, was good, digestion normal, tongue clean, and bowels regular. Pulse 104, temperature 99.5°, respirations 20. Her family history was good, and her mother, a healthy Irish lady, aged sixty years, accompanied her. Patient had been engaged as a concert singer every night up to midnight or later for past several years.

Examination revealed the following condition: The abdomen presented the appearance of a pregnant woman at about the sixth month. The fetus, however, could not be distinctly outlined, and there were no fetal movements nor heart sounds perceptible. On bimanual examination with fingers in the vagina, the cervix felt like one very extensively lacerated transversely, deeply excavated with a cauliflower like surface, and bled very readily. The uterus was enlarged, as noted before, quite fully movable, except on the left where it was attached to a solid mass about the size of an orange. The speculum was then inserted into the vagina and the cervix presented the appearance as I have described it.

Diagnosis: Carcinoma of a gravid uterus containing dead fetus of about five months growth, and a tumor in left side of the pelvic cavity, in all probability an extension of the carcinomatous condition.

I advised operation by abdominal section and a removal of the whole mass if possible, as the only chance to prolong life. The gravity of the case was presented to her and family in every detail as to her chances of recovery as well as to the seriousness of so extensive an operation in her present condition. The patient was very anxious to recover so that she could resume her concert singing, and she, as well as her family, were very desirous and anxious that I proceed with the operation at the earliest possible time. I assented to do so, provided counsel were called and my diagnosis confirmed. I then called in Dr. H. W. Howard, who examined the case and confirmed my diagnosis. The vital organs were in good condition, and examination of the urine showed it to be practically normal.

The patient was sent to the Pacific Hospital and put in the best possible condition for operation. She was very anxious to have the operation over with, asserting her every confidence that she would recover. Four days later, on the morning of March 30th, I operated upon her, Dr. Howard and Dr. Godin assisting. An incision was made from the umbilicus to the pubes, and on opening the abdomen, the pregnant uterus presented, and the fetus could then be outlined, but no signs of life were discernible.

I did a total hysterectomy as speedily as possible without

encountering any great difficulty or mishap, and found that the tumor in the left pelvic cavity was entirely separate and not adherent to the uterus as supposed. After the gravid uterus was removed in its entirety, I decided to remove the tumor. It seemed to fill the deep posterior cavity or hollow of the sacrum, apparently solid and immovable. Dr. Howard suggested that I better not attempt to remove it owing to its critical location, but I felt that the operation was not complete unless at least a very decided attempt should be made before concluding the operation.

By carefully breaking up adhesions by blunt dissection with my fingers I soon succeeded in loosening up the mass sufficiently to get my left hand well under it, when my forefinger of a sudden slipped into a spongylike cavity and about half a pint of creamy, cheesylike substance was compressed out. The greater part of it found its way out through the vaginal opening made by the hysterectomy. The iliac and sacral glands were so extensively involved that any further endeavors would have been fatal to the patient. The parts were thoroughly cleansed and the cavity packed with gauze, and drain carried down through the vagina.

The operation was then concluded in the usual manner by suturing the raw edges of the peritonæum from side to side, covering in all raw surfaces, the abdominal cavity thereby being completely closed, leaving the glandular cavity to drain through the vagina. The abdominal wound was closed in the usual manner in layers. The patient was under the anæsthetic two hours, but left the table in remarkably good condition. She came out of the anæsthetic with little or no shock and without any vomiting.

The fœtus in the meantime had been extracted from the uterus and it had apparently been dead for some days. It was well nourished and in the sixth month development.

A section of the cervix as well as a specimen of the broken down mass was sent to the pathologist who later reported: Carcinoma of the cervix and broken down epithelium of the large cell variety, showing the involvement of the deep iliac and sacral lymph glands.

The patient at the first did exceedingly well. The abdominal wound healed by immediate union, and the stitches were removed on the twelfth day. The vaginal drainage was quite profuse during this time. The patient continued to have a good appetite and good digestion, but seemed to be growing extremely nervous, when in the third week she showed symptoms of derangement of her mind. She became very talkative and insisted on getting up. She got little or no sleep, and required constant watching day and night up to the end of the fourth week, when her mental derangement abated. Her appetite and digestion during this time continued good; secretion of urine was normal, but bowels were loose; pulse varied from 130 to 100; temperature 100° F. to normal up to this time; and she was entirely free from pain.

From this on she made a steady gain. She left the hospital at the end of the fifth week and was removed to the home of a friend. She continued to grow stronger, and by the end of the sixth week she was up and around and her mental faculties again normal. At the end of two months she was allowed to go to the beach at Ocean Park, where, with her little daughter and her attendant, she was enjoying herself and in better health than she had been for many months.

The vaginal opening in the meantime had almost closed, leaving a very small fistulous opening from which there was an occasional slight bloody discharge. Five months after the operation, while lying in the sand on the beach, she had a slight hemorrhage from the vagina. She was taken to her cottage, where it immediately stopped. Examination revealed nothing but a small fistulous opening leading to the site of the tumor. Next day she was allowed to be up and around again. One week later she was attacked with a severe coughing paroxysm followed by a profuse hemorrhage of the lungs, and succumbed in about one hour.

The drama of this case may be concisely stated as follows: Pregnancy in a malignant uterus; death of fœtus at five months; operation, hysterectomy; mental derangement for three weeks; recovery, great happiness and enjoyment of life for three months; at the end of five months, pulmonary hemorrhage, death.

44 GREEN BUILDING.

## ANGULATION OF THE SIGMOID.

By THOMAS BRAY SPENCE, M. D.,  
Brooklyn, N. Y.,

Surgeon in Chief to the Methodist Episcopal Hospital.

Angulation of the sigmoid flexure, causing intestinal obstruction, partial or complete, has been described by Dr. Delatour (*Annals of Surgery*, November, 1905) and by Dr. Loroque (*Annals of Surgery*, November, 1906). In an earlier paper Dr. Ries (*Annals of Surgery*, October, 1904) reported a case as volvulus of the sigmoid that, according to his description, may possibly have been the same as these later cases, some of which were proved to be angulation, and his observations on mesosigmoiditis throw some light on the ætiology of the condition. So little has been written on the subject that it seems justifiable and desirable to report any additional cases and to remind the profession of the existence of a remediable condition which is sometimes very distressing and sometimes exceedingly dangerous.

Strictly speaking, the case which is here reported does not correspond exactly with the condition described by Dr. Delatour, but it was so manifestly an angulation of the sigmoid that it will be necessary to make his definition a little more inclusive. He says: "By angulation at the sigmoid, we mean that the intestine is so bent upon itself, at either the upper or lower end of the sigmoid, that complete or partial obstruction to the passage of the fecal current is established." In my case the sigmoid was bent upon itself at the middle of the loop, and in this way three abnormal angles were made. Angulation is therefore not confined to "either the upper or lower end of the sigmoid," and there seems to be no good reason for creating a new class for angulation between these two points.

CASE.—My patient was a man, thirty-nine years of age, a policeman by occupation. He was well until two years ago, when he began to have pain in his left side, at the location of the descending colon. This pain was sometimes intense, at other times it was a dull ache. At the beginning of the trouble his bowels became constipated and continued so; his faces were either scaly or fluid, never normal in character, and the pain was more severe when the constipation was most marked. There was a loss of weight of twenty pounds during the first year, and very little after that.

One year ago the patient was operated upon in a hospital in New York for a suspected cancer of the bowel, but was told that nothing abnormal had been found. He naturally experienced no relief from the operation and continued with precisely the same symptoms as before. At a later date he was treated in the medical ward of the hospital, and the question of a renal calculus was thoroughly investigated, but uranalysis and the x ray failed to corroborate a suspicion of stone.

The man was sent to me by Dr. Webster, who encountered him in his duties of police surgeon. After watching him for two weeks I agreed to perform an operation, for it seemed certain there must be some condition causing a partial obstruction of the intestine. As the pathological condition must have existed at the time of the first operation we felt that we could rule out tumors of any kind and bands of adhesions caused by the operation. We both had known of Dr. Delatour's cases, and angulation of the sigmoid seemed to us the most probable cause of the trouble, as well as the condition most likely to have been overlooked by the surgeon at the time of the first operation. A ventral hernia was present at the site of the original operation, and it was found that pressure on the descending colon elicited the typical pain which had been complained of for so long a time.

The incision included the scar of the former operation, and many adhesions were found in the left side of the ab-

domen. An angulation of the sigmoid, as described before, was found, and a thorough search revealed no other lesions. The loop of the sigmoid formed by the angulation was held firmly by adhesions, and, even after the adhesions were torn loose, the sigmoid immediately fell back into its faulty position when it was dropped into the abdomen. Because of the difficulty in overcoming the angulation, and because of the possibility of further trouble from the numerous dense adhesions along the course of the descending colon, it was deemed wise to cut out the colon by a short circuit between the small intestine and the sigmoid. An anastomosis was accordingly done, connecting the lower limb of the sigmoid to the ileum at a point about twelve inches from the ileocecal junction. Two rows of sutures were inserted, the inner one being a through and through stitch. The hernia was repaired by imbricating the layers of the abdominal wall.

On the eighth day after operation the patient vomited a small amount of blood and on the ninth day a much larger quantity. On the tenth day a small enema brought away a large amount of black fecal matter. The loss of blood from the stomach and bowel affected the patient markedly, but he soon reacted and was able to sit up on the nineteenth day.

There has not been any of the old pain since the operation, and at the end of four months there is a complete return of health and strength.

The happy result in this case seems to justify the operative procedure adopted, though it has probably not been done for this condition before. Loroque divided a short mesosigmoid for angulation, and relieved the obstruction, but this seems to me a procedure not wholly without risk to the integrity of the intestinal wall, because of the diminished blood supply. Delatour successfully treated some of his patients by fixing the sigmoid to the abdominal wall, and that is without doubt the operation best adapted to angulation at the upper or lower end of the sigmoid, but it would not have been effective in the case here reported. An anastomosis between the upper and lower limbs of the sigmoid would probably have answered the purpose, but the presence of so many adhesions along the course of the descending colon determined the operator in favor of a communication between the ileum and the lower part of the sigmoid.

130 SEVENTH AVENUE.

**Physicians in Politics.**—Referring to a State convention in Ohio of one of the leading parties, to which one hundred and five physicians went as delegates, the *Journal of the American Medical Association* remarks editorially: If better conditions are to be obtained in municipal and State government, it must be through an appreciation of the fact that the proper work of government is administration and not exploitation of the public. With this in view, there is no reason why the physician should not prove as good an administrator as his brother the lawyer, to whom the lion's share of political duties and opportunities has been awarded in the past. Three fourths of the work of the average legislative body to-day has to do with questions of administration. There is nothing in the personality, training, or experience of the successful physician that would render him less effective in dealing with administrative problems than the lawyer or the business man; neither is there any reason why a physician should not demand and exercise his full rights as a citizen, especially since he is far better fitted by education and experience for dealing adequately with many of the problems of modern legislation than is the average lawyer.

## Our Readers' Discussions.

### A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far they have been decided upon, the further questions are as follows:

LXXXIII. How do you treat seasickness? (Closed April 15, 1908.)

LXXXIV. How do you treat sunstroke? (Answers due not later than May 15, 1908.)

LXXXV. How do you treat cholera infantum? (Answers due not later than June 15, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisors will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL.

The prize of \$25 for the best essay submitted in answer to question LXXXII has been awarded to Dr. J. Russell Verbruyck, of New York, whose article appeared on page 788.

### PRIZE QUESTION NO. LXXII.

#### THE TREATMENT OF FRACTURE OF THE PATELLA.

(Continued from page 792.)

Dr. L. F. Barrier, of Louisville, Ky., observes:

The treatment of fractured patella may be conveniently described under two headings, viz.: Non-operative and operative, each having distinct advantages in selected cases.

When the fragments are easily replaced and surroundings are such as to render technique questionable, I prefer the nonoperative method, and treat them after the following manner: If I see the case before there is marked transudate into the joint I seek to limit this transudation by an elastic bandage and cold packs. The rubber bandage may be used for this, or dry sea sponges can be bound tightly upon the knee while dry, and then the sponges are wet with cold water. The swelling of the sponges keeps an even pressure and limits transudation, and at the same time applies the cold. This method is also useful to promote absorption if transudation has occurred. In cases with extreme transudation the joint should be aspirated carefully.

After the swelling and fluid have been made to subside, the permanent dressing is put on. The knee is fully extended with a posterior splint and the thigh moderately flexed to relax the quadriceps extensor tendon. The fragments are now accurately adjusted and held firmly while the assistant tightly adjusts two inch strips of adhesive plaster by fastening the middle above the upper fragment and then attaches the ends spirally around to the calf of the leg. Another is attached in the same manner below the lower fragment and pulled upward, to be attached spirally to the posterior aspect of the thigh. After sufficient number of these strips have been firmly applied, a strip of plaster is well fastened over the top of the patella, so that tilting of the fragments cannot take place.

The splint is held in place by straps so as to allow the limb to be exposed for massage twice or three times daily for ten or fifteen minutes for the first few weeks. At the end of three or four weeks passive motion is begun. This must be very limited at first and not sufficient to separate the fragments, but just enough to prevent adhesions to the joint surface. The range of motion must be very gradually increased for several weeks, during which time the patient should be up on crutches with the limb encased in a plaster cast, which may be split and sprung off for passive motion, or in some form of splint that will permit easy removal.

At the end of eight or ten weeks the splint should be removed and the limb well bandaged, and the patient allowed to walk with a cane, but stair climbing or any sort of lifting must be avoided for several months.

This method gives good functional results in a large percentage of cases, but it requires much longer time for recovery than does the operative method.

The operative method is always to be preferred when surroundings are so that ideal technique can be had. The great danger lies in infecting the large serous sac of the knee joint.

In none save compound fractures should operative procedures be instituted until the acute reaction has been made to subside. Then with the most rigid asepsis the joint should be opened and washed free of blood clots with warm saline. The patella fragments are pulled together by hooks and the periosteal fringe removed from between them, and sutures of chromic catgut introduced through the fascia and tendinous structures and the periosteum, and rarely through holes drilled in the bone, so as to coapt the broken surfaces nicely. The method of placing the sutures will, of course, depend upon the line of fracture and the number of fragments. If the bone is fractured into several pieces the fragments can usually be held best by encircling the entire bone with the catgut.

The wound is now closed with catgut and the limb put upon a posterior splint. It is also well to put an adhesive plaster dressing on like the one described above, so the fragments cannot be accidentally torn apart.

Massage must be kept up, and at the end of two or three weeks gentle passive motion instituted, and the patient is allowed to be up on crutches with a light splint.

If the fracture is compound the joint must be well irrigated with 1 to 10,000 bichloride of mercury solution, followed by saline. The small, ill fitting fragments are removed and the others sutured in place and the joint drained for a time.

Occasionally the patella is so badly comminuted by direct force that it is better to remove it entirely than to attempt to unite the pieces. In a case of this kind the fascia is saved so far as possible and a tendinous flap made from a part of the tendon of the quadriceps, which is turned down and sutured to the ligamentum patella, and the fascia preserved after removal of the bone.

In these cases it is well to surround this lengthened tendon by fatty tissue, so as to form a sheath as free from adhesions as possible.

*Dr. G. H. Palmerlee, of Detroit, Mich., states:*

In the treatment of fractures of the patella there are three indications to be considered, no matter whether the treatment is to be operative or nonoperative. The first thing to do is to stop the hæmorrhage and effusion into and around the joint; second, secure the approximation of the fragments until union occurs; and, third, restore the function of the joint and overcome atrophy of the quadriceps extension muscle.

A good method to secure a quick absorption of the effusion indicated, no matter whether the further treatment is to be operative or nonoperative, is to apply a well padded posterior splint, elevate the foot, and bandage the knee from below upward with a rubber bandage, making firm and even pressure, but not tight enough to interfere with the circulation, leaving the bandage on for two days, then most of the blood or exudate will be absorbed. Massaging the knee twice daily for five minutes will often prove useful. Aspiration is sometimes employed, but does not prove altogether satisfactory on account of the blood clots present.

Various subcutaneous operations have been devised, and since it must be admitted that they incur some risk of infection without securing accurate apposition of the fragments, then it is obvious that if any operative procedure is undertaken, the open operation should be the one of choice, since by no other method can the fragments be accurately approximated.

Operative treatment is absolutely contraindicated unless the strictest aseptic technique can be carried out; and it is contraindicated in old people, or where the skin is much bruised and there is some doubt of not obtaining primary union of the skin wound.

It seems to be the consensus of opinion among surgeons who operate a good deal that the operative treatment gives the best results, as the hæmorrhage is at once relieved; the tear in the aponeurosis can be repaired better, the displacement of the fragments is overcome, and the chances for a bony union are more favorable.

Some surgeons prefer to wait a few days before operating, but it is safe to operate after the first twenty-four hours. A curved incision is made, the fascia cut through, and the fracture exposed. The joint should then be thoroughly washed out with a saline solution or sterile water; or if antiseptics are used they should be very weak, flushing the joint after their use with sterile water.

The torn aponeurosis and periosteum, which are turned over the edges of the fracture, are cut away and retracted. The patellar fragments and the aponeurosis may be united with silver wire, catgut, or kangaroo tendon. The tendency now is to use an absorbable suture, and it is of as great importance to suture the aponeurosis as it is to suture the patella itself. Unite the aponeurosis and periosteum in front of the patella with three sutures, and suture the lateral tears with at least two sutures. Silver wire inserted through holes drilled in the patella is still extensively used. It is not necessary to use a metal suture or unusually large catgut or kangaroo tendon, as it does not require much to hold the

fragments together, since we depend on a splint principally for immobilization.

Rubber gloves should be worn and the wound handled as little as possible; drainage is not used, and the skin is closed with silkworm or catgut. The leg should now be wrapped in sheet wadding from the heel to the hip; a plaster cast is then applied and left on for six weeks; at that time the fragments are usually firmly united; the cast should then be removed, massage and passive motion may be safely begun, and the patient allowed to go about on crutches, bearing but little weight on the injured leg, the injured joint being protected by a leather knee cap or elastic bandage.

Old cases, where the knee cannot be flexed to a right angle, or if it is impossible to extend the knee or walk without limping, a much better functioning joint can be obtained by operating; the fibrous tissue is dissected out, the edges of the fragments freshened, and sutured with number four catgut or kangaroo tendon, or it may be necessary to remove the fragments and suture the patellar ligament to the quadriceps extensor tendon; occasionally the upper fragment will have to be detached from the femur.

Perrassier's method consists in turning down a square flap of the anterior fibres of the quadriceps tendon over the broken patella, and suturing it to the patellar ligament below; this prevents eversion of the upper fragment.

The nonoperative treatment is indicated in very elderly people, and when the fragments can be easily approximated, and when circumstances do not permit of strict aseptic precautions, or when the surgeon is not accustomed to doing much operating, and not in the habit of daily asepsis. The injured leg should be placed on a well padded (particularly at the heel) posterior splint, extending from below the heel to the hip and elevated about six inches; the next important thing is to reduce the swelling; probably nothing will do this as readily as a rubber bandage, applied firmly, but not tight enough to interfere with the circulation. The application of an ice bag is of some service, not only in reducing the swelling, but relieving the pain. Massage is also of service in getting rid of the exudate. In a few days the swelling will have subsided, and not until then should an attempt be made to approximate the fragments. Do not apply a plaster cast until the fragments have united, since the joint cannot be inspected, and the fragments may become widely separated. The splint being applied, the upper fragment is held down by a strip of zinc oxide adhesive plaster passed just above the upper fragment, extending downward in such a manner as to pull the upper fragment down, the ends fastened to the splint; the lower fragment is now held in a similar manner, the adhesive strip placed below the fragment, extending upward and backward, and fastened to the splint; another strip is placed over the edges of the fragments, which prevents them from tilting outward after they are approximated; two or three strips may be used instead of one, overlapping each other a little; the plaster strips need not be removed until six weeks have passed. Union has usually taken place in that time.

If a plaster cast is used it should be split down

the median line before it hardens in order that it may be removed at intervals for massaging; at the end of six weeks the patient may be allowed to bear some weight on the limb, with the help of crutches, while wearing a removable splint such as a knee brace, or leather knee cap, and at the end of two months the patient may be allowed to walk with a cane. The knee should be protected by an elastic bandage for another two months, and sudden movements should be carefully avoided during this time, since there is a liability of refracture.

*Dr. Sidney J. Sondheim, of Reading, Pa., says:*

Upon having made the diagnosis of fracture of patella, two methods of treatment present themselves for consideration, operative and nonoperative. What are the influencing factors which should determine your decision?

1. Age and physical condition of patient. Operation unless open fracture of patella should never be performed in person over sixty, and if not in good health should not be performed at any age.

2. Environment as to modern hospital and expert surgical skill. Since we are dealing with one of the largest joints of the body, with its numerous synovial sacks and consequent danger of infection, operation in simple fracture should, as a rule not be performed unless in a hospital with all modern equipments and expert surgeon and assistant.

3. Occupation of patients. If a man's occupation is such that full use of his leg is a necessity to him for a livelihood, or if compelled to get back to work in short time, operative procedure when successful gives better and quicker results.

4. Character of fracture. All open fractures of patella should be sutured at once. Simple fractures, with wide separation of fragments and extensive lacerations of capsule or when comminuted, give, under favorable circumstances, better results when sutured. Secondary fracture of patella, long fibrous union in an old fracture, fracture healed so as to prevent motion of leg, all indicate operative procedure under favorable circumstances.

A decision should not result from consideration of any one factor, but of all of them. It is always to be remembered that with operative method, even under the best of conditions, there is danger of infection, with stiff joint, perhaps amputation, and death. With nonoperative procedure, if a failure, we can always resort to operative method at any time, although perhaps with less favorable local conditions.

Nonoperative method.—Whatever method of treating fracture we adopt we have the following indications to meet always: 1. Removal and prevention of swelling as far as possible. 2. Reduction and apposition of fragments. 3. Complete immobilization of fragments until union is secure. 4. Restoration of functions of knee joint.

If seen early swelling can often be prevented by equal pressure over joint by elastic rubber bandage or by sponges beneath a bandage, which are then saturated with water or lead water and laudanum, which will cause the sponges to swell and give equal pressure over joint. Elevation of leg and massage two or three times daily are routine measures.

These measures also apply to reduction of swelling when not seen early. If swelling is very persistent and effusion great, an incision or aspiration with needle with most careful precautions to prevent infection may be done.

The swelling having been reduced, we next consider reduction and fixation of fragments. To secure complete relaxation of quadriceps extensor muscle we extend and elevate the leg. A posterior or ham splint of plaster of Paris or wire extending from about one decimetre above the heel to the upper part of the thigh, held in place by three or four bands of adhesive, which go around the leg, and prevent its flexion, is next applied. The upper fragment is drawn down and held in place by traction of a strip of adhesive placed above the fragment and running obliquely down the leg below the fragment. The lower fragment is similarly fixed. As the swelling subsides the upper adhesive strap becomes loose and must be frequently adjusted. A third strip of adhesive is placed directly across the fracture and around the leg to prevent tilting of fragments. To facilitate action of adhesive a splint can be placed above the quadriceps. Lateral splints may now be applied and fastened and the leg elevated. The splints, except the adhesives, should be daily removed and the leg thoroughly massaged.

At the end of four to six weeks all dressings can be removed, and plaster cast extending from below fulness of calf to groin can be applied. This should be slit, so as to be readily removed for massage and bathing, and fastened again firmly after each such treatment. Slight passive movements of leg may now be adopted, and patient allowed to go about on crutches. At end of eight to twelve weeks patient may walk with cane, and passive movement should be increased. At the end of five to six months splint may be removed, bandages applied, and leg gradually used.

Operative treatment.—I shall dwell very lightly on this phase of the subject. There are two methods of fastening fragments by suture, subcutaneous method and open method. Each has its indications, advantages, and disadvantages. They are, briefly: When we can obtain good apposition with fracture transverse and in absence of most favorable operable conditions, the subcutaneous method is to be preferred. When we have wide separation or fragmentation and great swelling, with tearing of ligaments and modern hospital necessities, open method is to be preferred.

Subcutaneous method.—Under strict asepsis thrust a knife through the skin and ligamentum patellæ just below middle of lower fragment. Pass pedicle needle through this wound beneath patella, above upper fragment, through insertion of quadriceps, and through incision made in skin at this point. Thread with strong sterilized silk and draw out through lower opening, unthreading the needle, leaving the thread in place. Now pass needle through the same lower opening, above patella, to the upper opening, again thread needle, and draw through the lower opening. We now have the ligature looped about the patella. Displace any tissue which lies between the fragments by briskly rubbing them together, and tie suture tightly. Close wound, apply a posterior splint, and preferably fig-

ure of eight bandage, or adhesive plaster. Passive movements may be begun in from ten to fourteen days, and plaster of Paris dressing in three to four weeks.

Open method.—Unless an open fracture, when the joint should be widely opened, we may use three forms of incision—transverse, vertical, or oval incision (Cheyne). The latter two are preferable, since in former there is some danger due to flexion of the leg bringing tension along the line of incision, and certainty of opening prepatella bursa. With most careful aseptic precautions, the joint is opened by one of the methods cited. The clots are removed by flushing the joint with sterilized normal saline solution, or a 1 in 10,000 bichloride solution. Loose particles of bone are removed, and holes are bored in the patella from upper to fractured surface, both superficial and deep. Blood and fibrous tissue are now removed from the approximating surface, and suture material is introduced. If silver is used, after twisting and smoothing down, the torn capsule is sewed and fibrous tissue over patella is sewed. The skin suture is closed, and Post splint is applied until the skin incision is healed; then the knee is placed in plaster cast. Daily massage is employed, and patient can be about usually in three weeks in plaster cast. Movement of patella may be begun quite early to hasten the free use of the limb, which can, as a rule, be freely used in a few months.

(To be concluded.)

## Therapeutical Notes.

**Treatment of Red Nose.**—In reply to an inquiry regarding the treatment of red nose several contributors to *The British Medical Journal* for April 11, 1908, make suggestions. It is noted that each case requires treatment for the cause. A lady who had a very ugly red nose was treated with the following, which acted well:

R Sulphur. praecip., calaminae, .....ãã gr. xxx;  
Ac. carbol, .....℥ vj;  
Lanolin. pur., .....3j.

Sig.: After steaming the nose over boiling water, apply this ointment at night.

R Fer. am. cit., .....3j;  
Liq. arsenical, .....3j;  
Aq. chlorof., .....ad 5vj.

Sig.: 3ss three times a day after food.

In another case the administration of laxative doses of cascara sagrada every night, and the use of the following lotion, proved effective:

R Calamine, .....℞. N;  
Bismuth trinitrate, .....℞. N;  
Acid. hydrocyanic, dil., .....3ij;  
Pulv. tragacanth co., .....3j;  
Aq., .....ad 5j.

M. Sig.: For external use.

A little to be sponged over the nose every night at bedtime and allowed to dry. Another practical hint is always to use the tragacanth powder for cosmetic lotions instead of pulv. acaciae.

The pernicious habit of passing the smoke through the nostrils in cigarette smoking was blamed for the appearance of a glaringly red nose in a youth who was addicted to the habit.

**Medication by Cataphoresis.**—*The Prescriber* for April, 1908, gives a brief account of the cataphoretic method of introducing medicines into the system. Many applications of the principle are now in use. It is well known that when a current of electricity is passed through a solution of a chemical salt, the latter becomes decomposed or electrolyzed, the base as a rule going to the negative pole and the radicle to the positive pole. This is accounted for by the theory that the molecules exist as ions, or electrified particles of matter, those of the base and radicle carrying respectively their negative and positive charge of electricity. These ions are dissociated by the electric current which appropriates them to the corresponding complementary poles of the circuit. Advantage is taken of this principle to force medicinal substances in the ionic state into the tissues of the body. If a solution of, say, quinine sulphate be used to soak a pad covering the positive pole of a battery, this pole applied to the skin, and the negative pole so arranged that the current may pass through the tissues, the quinine ions will seek the opposite pole, and in so doing will pass through the tissues with the current. The ions thus forced into the body enter not only into the lymph spaces, but into the cells themselves, becoming a part of the protoplasm, and consequently their effects are much more pronounced. The principle may be shown experimentally by placing a piece of raw beef between the poles of a battery, the negative electrode being covered with blotting paper soaked in a solution of potassium iodide, and the positive electrode similarly treated with starch solution. On applying the current the iodine ions pass through the beef to the positive pole, the paper on which soon shows the blue color of starch iodide. This process, described as cataphoresis or ionic medication, has been tried with considerable success in the case of such drugs as break up into ions. Relief of tabes dorsalis by cocaine ionization was described in the *British Medical Journal* in January, 1905, and since then a number of cases have been successfully treated by this method. Dr. Lewis Jones (*The Hospital*, October 20, 1906) and Dr. Dawson Turner (*The Prescriber*, September, 1907) have both reported on cases of rodent ulcer cured by means of zinc ions. The process is extremely simple—a portable battery with wires has a disc or rod of zinc attached to the positive pole. The zinc is covered with a few layers of lint wetted with a five per cent. solution of zinc sulphate and applied to the ulcer previously cleaned. The negative electrode is either held in the patient's hand or placed in a basin of salt water in which the hand is immersed. The current is gradually raised to 40-60 milliamperes, or as much as the patient can bear, and continued for thirty seconds. The surface of the ulcer is now white and dry, and another application may be made in a week or a fortnight; two or three applications usually being sufficient. A burning sensation like that of a mustard plaster is felt, which in sensitive patients may be counteracted by means of cocaine. Other applications of the ionic treatment are suggested. Copper ions have been found efficacious in destroying the para-

site of ringworm, and magnesium ions have cured multiple warts on the hands. The chlorine ions have proved useful in fibrous ankylosis and sclerosis, and a case of Dupuytren's contraction, which had lasted fifteen years, was recently cured in the same way. The salicylic ion has been found to relieve tic douloureux which had proved refractory to other remedies. Giovine (*Riforma Medica*, November 2, 1907) records cases of gonorrheal arthritis and tabetic arthropathy of the knee, in which the iodine ions from potassium iodide gave good results, also a case of sclerodactylia, which was cured by application of chlorine ions. The difficulty in the way of treating lupus has so far lain in the fact that the bacillus contains a large proportion of fat, which is a complete nonconductor of electricity. In applying the ionic treatment it should be borne in mind that basic ions move from the positive to the negative pole, consequently the medicament must be introduced at the opposite pole. Acids move in the opposite direction. The limitations of the method are that the ions can be introduced only very slowly, and a prolonged application, possibly under chloroform, would be necessary to reach parts at great depth.

**Prescription for Obstinate Hiccough.**—The following prescription is recommended by *The Hospital* as being successful in cases of obstinate hiccough:

R Spirit of nitroglycerin, ..... viii;  
 Spirit of chloroform, ..... 5iv;  
 Water, ..... q. s. ad 5iv.  
 M. Sig.: One fourth part for a dose; to be repeated for three or four doses.

**Tannin in Postpartum Hæmorrhage.**—In the Vaud, where the women lead very laborious lives and have very large families, postpartum hæmorrhage, due to uterine inertia, is of very frequent occurrence, and the country practitioner is at times at his wits' end for an effective method of treatment. The usual means—ergotin, massage of the uterus, bimanual compression, ice, injections of hot water, with or without tannin, and even plugging with gauze or the fist—having failed him. In such a case Renaud (*Revue médicale de la Suisse romande; The Practitioner*, April, 1908) tried the effect of gauze powdered with tannin, and the effect was almost immediate, although the uterine contractions remained very weak. He thereupon had prepared some gauze, impregnated with ten to fifteen per cent. of tannin, which was cut into suitable lengths for packing the uterus, and then sterilized by high pressure steam. These are packed in parchment paper, which keeps them aseptic, portable, and ready for instant use. He has made an extensive use of this hæmostatic packing, and has always obtained a successful result, with rapidity and certainty in cases of postpartum hæmorrhage, and also in cases of severe metrorrhagia at the menopause, in which packing has been necessary. As the dressing is "hæmostatic" and not "antiseptic," every care must be taken in introduction to avoid soiling against the labia and external parts of the genital region, and the packing should not be allowed to remain in the uterus for more than from twelve to twenty hours. This allows ample time to insure final coagulation.

## NEW YORK MEDICAL JOURNAL

INCORPORATING THE

Philadelphia Medical Journal  
and The Medical News.*A Weekly Review of Medicine.*

Edited by

FRANK P. FOSTER, M. D.,  
and SMITH ELY JELLIFFE, M. D.

Address all business communications to

A. R. ELLIOTT PUBLISHING COMPANY,  
Publishers,

66 West Broadway, New York.

PHILADELPHIA OFFICE:  
371½ Walnut Street.CHICAGO OFFICE:  
160 Washington Street.

SUBSCRIPTION PRICE:

Under Domestic Postage Rates, \$5; under Foreign Postage Rate,  
\$7; single copies, fifteen cents.Remittances should be made by New York Exchange or post  
office or express money order payable to the A. R. Elliott Pub-  
lishing Co., or by registered mail, as the publishers are not  
responsible for money sent by unregistered mail.Entered at the Post Office at New York and admitted for  
transportation through the mail as second class matter.

NEW YORK, SATURDAY, MAY 2, 1908.

## THE ARMY MEDICAL CORPS BILL SIGNED.

On April 23d President Roosevelt signed the bill enacted by Congress providing for the reorganization of the Medical Department of the United States Army. The measure was printed in the *New York Medical Journal* for April 18th, on page 763, and has already been commented on. The essential features of the bill are the provisions for a material increase in the number of officers—for a surgeon general with the rank of brigadier general, fourteen colonels, twenty lieutenant colonels, one hundred majors, and three hundred captains or first lieutenants, all of whom are to have rank, pay, and allowances of officers of corresponding grade in the cavalry arm of the service. Assistant surgeon generals are to be recommissioned, with the rank of colonel; deputy surgeon generals, with the rank of lieutenant colonel; surgeons, with the rank of major; assistant surgeons as captains and first lieutenants, the lieutenants to be promoted to the rank of captain after three years' service.

The reserve corps which is provided for in the measure is to be made up from surgeons in civil life, who will be given the rank of lieutenant, but without pay, save when assigned to active service. The bill will make thirty-two vacancies in the corps in addition to the twenty-seven already existing. Examinations will be held on May 4th and on August 3d to fill these vacancies. The bill providing for an increase in the pay of the officers and enlisted men of the army, including the officers of the medical corps, has not yet been enacted, some

objection having been made to its passage, although it seems probable that it will become a law before the close of the present session of Congress.

## THE CRAZE FOR NOVELTY IN BOOKS.

*Le roi est mort, vive le roi!* Hardly is the first demand for copies of a new medical book satisfied than its legitimately expected further sale is found to be almost impossible. The cry is set up that it is out of date, and many a copy that has been ordered is returned to the publisher with the more or less indignant comment by the person who ordered it that he will not put up with an old book. And yet the book may be a very recent one and quite abreast with progress in the subject with which it deals. The unreasonable purchaser demands that everything shall be "hot off the griddle"; he wishes to see the current year designated on the title page. In most instances the demand is utterly senseless. Every year there are issued many medical books which will never grow old in the sense of becoming useless. It is our own fault if we blink this fact and virtually force the publishers into the issuance of new editions, or what purport to be new editions, of such books. It must be admitted, of course, that in some of the departments of medicine a book really does get out of date, however satisfactory and complete it may originally have been, but the deficiencies of such a book may always be supplemented by recourse to the medical journals; to make up for such deficiencies is one of their chief functions.

So long as this demand for a new date on the title page exists publishers will find it expedient to resort to certain devices which are not always harmless. One of these is that of changing the date annually, whence great injustice to the author often results if he has not been allowed to revise the text. Fancy, for example, a medical dictionary dated 1908, but really published in 1900. Between those two dates multitudes of new words have come into use, and many fresh meanings have been given to old ones. Necessarily these verbal novelties do not appear in the book, and the unthinking revile the author and despise his careful and really meritorious work. A publishing house has been known to defend this misbranding procedure by professing that it had only desired to show that the book was a "live" one, whereas it was the real purpose of the house to galvanize a dying book into such a semblance of vitality as might lead to its continued sale.

Can we be censorious with the publishers for resorting to such a practice? Their fault, it seems to us, lies chiefly in their resorting indiscriminately to a device which, if applied only to certain books,

would work no real injustice, whatever might be thought of its abstract right or wrong. So called "new editions" are often only fresh printings, and the practice of printing the misleading announcement on the title page is even more detrimental to the author's reputation than the mere change of date to which we have alluded. We are glad to be able to say that publishers are resorting to these devices less and less, and that there are not a few houses which have never yielded to the temptation. Let us assist them in resisting it by showing ourselves permanently appreciative of good books, even if they are a few years old, for, save in a few fields, such as that of bacteriology and radiography, in which progress at the moment is rapid, the difference of a few years in the date of the edition of a book is not a serious matter.

#### SCHOOL CHILDREN'S EYES.

We are glad to learn that the Association of Women Principals of the Public Schools, of New York, has taken up certain important questions connected with the care of school children's eyes. Physicians have for years been convinced of the deleterious effects of the maddening glare given out by the glazed paper which is used in books when it is thought desirable to illustrate them with half tone engravings. In some foreign publications we find half tones handsomely printed on paper which is almost if not quite unobjectionable so far as glare is concerned. Our French and German exchanges, for example, afford ample evidence of this. For certain trade reasons, we suppose, such paper is not to be obtained here at all or only at prohibitive prices. So we imagine that the half tones will have to go if we are to get rid of the highly glazed paper.

Many of the half tone engravings are in a high degree artistic, and they have the advantage of presenting undeniable reproductions of photographic pictures, with all their good points and all their bad ones. For all that, however, we prefer woodcuts for most purposes. Where are the half tones that present such lucid depictions as are to be found, for instance, in the old woodcuts of Sappey's *Anatomy*? But the woodcuts must be of a high order of excellence, and to whom shall we turn now for such work in woodcutting as we were accustomed to a few decades ago? Doubtless a few accomplished wood engravers still survive, but their numbers must be steadily diminishing. Wood engraving, alas, is almost a lost art. As a rule an engraving on wood is more expensive than a half tone block, and doubtless that fact will stand in the way of a general return to the wood, but it ought not to prevent our taking all practicable steps to safeguard

the children's eyes. The semidiagrammatic is often wonderfully effective in the art of illustration, and it seems to be more readily attained by the wood engraver than by the process worker—effective, we mean, not solely from the artistic point of view, but also from that of instructiveness. Surely that consideration ought to weigh against the objection to woodcuts on account of their cost.

Another point brought out by the association is that of the strain on vision caused by following long lines of type, even if the type is large. Short lines with suitable leading permit of the use of comparatively small type with far less fatigue to the reader's eyes than must result from the employment of long lines. The difficulty comes in when the reader has finished a line and seeks to retrace his course so as to take up the next one; it is almost as trying as that of sighting a rifle fitted with a wind gauge. It is unjust to impose such a difficulty on any reader; in the case of a young child (studying, not reading for amusement) it amounts to cruelty. Evidently there are many of our school books which can be materially improved from the mechanical point of view, and we hope that the necessary improvement will not long be deferred. The same may be said with regard to medical books.

#### THE ÆTIOLOGY OF MYCETOMA.

Musgrave and Clegg (*Philippine Journal of Science*, December) report a case of Madura foot which they observed in Musgrave's clinic in St. Paul's Hospital. They succeeded in isolating a streptothrix from the tissues of the foot which has some morphological and cultural differences from actinomycetes and from *Streptothrix Madura* (Vincent), as well as from the streptothrix isolated from cattle in Guadeloupe by Fullerton, and from the streptothrix isolated from a brain abscess in man by Fullerton. Musgrave and Clegg have named the organism isolated by them *Streptothrix Freeri*, after Dr. Paul Freer, director of the Bureau of Science of Manila.

They have succeeded in killing monkeys, guinea pigs, and dogs by intraperitoneal inoculation of the pure cultures of the streptothrix. In monkeys a tumor is produced at the site of the inoculation which contains the organism. Death is apparently due to a toxemia. In guinea pigs metastatic abscesses containing the streptothrix were found in the liver, the diaphragm, the omentum, the mesentery, and the spleen, from which the streptothrix was obtained in pure culture. By inoculation of pure cultures of the streptothrix, and by inoculating material from the human foot, after amputation, into the feet of monkeys, a disease was produced in the

monkeys similar to that in the amputated foot. The disease is distinct from actinomycosis, and it appears from this report that the Madura foot of the Philippine Islands is due to an organism which differs in some respects from that causing Madura foot in India.

### TRAUMATISM AND TABES DORSALIS.

In many cases of mechanical injury sustained by a person in the performance of his work it is difficult to form a just estimate of what damages, if any, the injured individual is entitled to; but perhaps it will be easier when we have accumulated data concerning a large number of cases. One case that seems to be of considerable interest is recorded by M. Tourey-Piallat in *La Clinique* for April 17th.

On the 1st of March, 1906, a man employed by a railway company at the Bourgoin station was struck in the back by a piece of falling baggage, but not knocked down. The second article fell upon him and prostrated him. Then the third, a heavy wicker hamper, fell on his right leg and broke it. A surgeon in the employ of the company attended the man. In the course of the ensuing July, the injured limb being still rather weak and incapable of full power of motion, the man was sent to the Zander mechanotherapeutic institute at Aix-les-Bains. This was by the advice of the railway surgeon. In August there appeared pronounced signs of tabes. The patient was then taken back to Bourgoin, where the malady became more and more decided, at last rendering him quite incapable of work.

The victim, regarding his ataxia as the result of the fall, sued for damages to the amount of two thirds of his pay. The company, challenging his ability to establish a connection of cause and effect between the accident and the disease, estimated that twenty per cent. only of his disability was attributable to the injury, that being apparently the amount which the traumatic lameness added to the incapacity produced by the locomotor ataxia. A medical expert appointed by the court coincided in this estimate, and the court held accordingly. The expert reported that tabes of purely traumatic origin was not generally admitted, and that in the particular case under consideration the length of time that had elapsed after the man was able to rise and walk before the ataxia appeared showed that the traumatic weakening of one lower limb had simply somewhat aggravated the disabling effect of the tabes.

M. Tourey-Piallat thinks that the decision was a just one, and he intimates that it makes amends for the failure of the law to take antecedent morbid

conditions into account. If, he says, the injured person was previously affected with a latent disease or infirmity, and an accident hastened its evolution, the injury would be held to be the sole cause of the final condition. In the Bourgoin case the tabes could not with certainty be held to have been an antecedent morbid state, and its development could not, therefore, be looked upon as due to the injury. Thus, indeed, may the law secure something like an equalization of right and wrong in a general way, but it is not easy to see how it mitigates the sad lot of the poor Bourgoin employee. In this connection the reader may find it interesting to refer to the article entitled *Injuries and the Previous Condition* in our issue for April 25th, on page 795.

### A NOVEL VIEW OF THE MEDICAL LICENSE.

The *Lancet*, of London, puts forth the suggestion that authority to treat disease by drugs or otherwise be granted to unqualified persons upon payment of a license of 500 pounds. In defense of this suggestion it is pointed out that brewers, publicans, and tobacconists have to pay for a license now, though the state does not guarantee the purity of the articles sold by them. The *Lancet* despairs of the suppression of unqualified practice and quack medicines by law, offers the suggestion of a high license fee as a partial solution of the problem of regulating the practice of medicine by law, and seems somewhat surprised that so simple and, to the state, profitable a scheme has not been approved of. The suggestion will strike American readers as being both absurd and unwise. In fact it places the state in the attitude of reaping a benefit from the issue of licenses to do wrong and as being on a par with the sale of indulgences. To the medical profession on this side of the Atlantic the most surprising feature of the suggestion is that it should emanate from so sane and so conservative a source as the *Lancet*.

### THE LATE PROFESSOR CORNIL.

Victor Cornil, the great pathological histologist, died on April 14th at Menton, whither he had betaken himself in the hope of regaining his strength after a severe attack of bronchopneumonia. He was a little more than seventy years old at the time of his death. In this country we are accustomed to thinking of him mainly in connection with the *Manuel d'histologie pathologique*, which he wrote in conjunction with M. Ranvier. In the *Presse médicale* for April 18th M. Maurice Letulle justly

speaks of him as a master of pathological anatomy, a worthy successor of Cruveilhier, Lebert, Vulpian, and Charcot, all of whom had been his teachers.

It was not in science alone that M. Cornil achieved distinction. He was active in political life, and at a critical period in the affairs of the French nation Gambetta placed him at the head of a department. He served also in the Chamber of Deputies and subsequently in the Senate. After years of effort he and M. Brouardel had the satisfaction of seeing the Senate, in 1902, pass the public health bill which the Chamber had already adopted. With all his political activity, M. Letulle reminds us, Cornil never ceased from his devotion to scientific investigation. As a man renowned in medical science and as a statesman, he may fittingly be classed with Virchow. There have been few such men in the medical profession. There ought to be many more, for there is no incompatibility between the prosecution of science and the furtherance of political affairs.

### News Items.

**Changes of Address.**—Dr. Max Bernstein, to 2 East One Hundred and Seventeenth street, New York; Dr. Julius London, to 763 East One Hundred and Fifty-sixth street, New York.

**A Dinner to Professor Martin, of Berlin.**—A subscription dinner is to be given at the Hotel Astor on the evening of June 10th, as a farewell ceremony in honor of Geheimrat Professor August Martin, of Berlin.

**Medical Society of the George Washington University.** At a meeting of this society, held on Thursday evening, April 23d, Professor E. A. Schäfer, of Edinburgh, delivered a lecture on Internal Secretions.

**Medicolegal Society of Philadelphia.**—At a regular meeting of this society, held on Tuesday evening, April 28, Dr. F. X. Dercum read a paper on Expert Testimony.

**The Boston Medical Society** held its annual meeting recently and elected the following officers: President, Dr. William F. Gay; vice president, Dr. A. J. Hurwitz; treasurer, Dr. Rufus K. Noyes; financial secretary, Dr. Frederick J. Bailey; corresponding secretary, Dr. L. A. Herman.

**Atlanta School of Medicine.**—The annual commencement was held on April 22d, and forty-nine young doctors, representing twelve states and two foreign countries, received their diplomas. Dr. John C. Olmsted delivered the annual address.

**Vital Statistics of Minneapolis.**—During the month of March, 1908, there were reported to the Department of Health of Minneapolis 262 deaths from all causes, 154 males and 108 females. There were 22 still births. One hundred and forty-four marriages were reported and 517 births.

**The Kentucky State Association of Railway Surgeons.** The fourth annual meeting of this society will be held in Louisville, Ky., on May 12th and 13th. All who are desirous of taking part in the discussions will please notify Dr. Cuthbert Thompson, Broadway and Third street, Louisville, Ky.

**The Mercy Hospital of Canton, Ohio,** will soon be opened. It is to be a non-sectarian general hospital and will occupy the site of the home of President William McKimley. The property was purchased by Mr. Ross Klorer for \$20,000 and made over to Bishop Horstman for hospital purposes.

**Connecticut River Valley Medical Association.**—The annual meeting of this association will be held at Bellows Falls, Vt., on Tuesday, May 5th. Papers will be presented by Dr. F. M. Dinsmoor, Dr. A. L. Miner, Dr. N. P. Wood, and Dr. S. W. Hammond, which will be followed by discussions and reports of cases.

**Plague in Guayaquil, Ecuador.**—According to newspaper reports, plague has appeared in Guayaquil, and during the four days ending April 22d twenty cases of the disease, with nine deaths, were reported. Among those who have died of the disease is Flores Ontaneda, a chemist, who was engaged in preparing Haffkine's prophylactic.

**Laying of Corner Stone of New College of Physicians Building, Philadelphia.**—The ceremonies of laying the corner stone of the new building of the College of Physicians took place on Wednesday afternoon, April 29th. After prayer by Bishop Whitaker, the president, Dr. James Tyson, delivered a short address, and the corner stone was then laid by Dr. S. Weir Mitchell.

**Buffalo, N. Y., Academy of Medicine.**—A special stated meeting of the academy was held on Tuesday evening, April 28th, to consider the question of incorporating the academy and of securing a permanent home for the organization. The scientific programme of the evening was furnished by the Section in Obstetrics and Gynecology. The principal paper was entitled *My Obstetrical Experience*, and was read by Dr. J. W. Grosvenor.

**Richmond, Va., Academy of Medicine.**—The following papers were read at a meeting of this academy, held on Tuesday evening, April 28th: *Nature and Treatment of Fever*, by Dr. William S. Gordon; *Diagnostic Significance of Chills*, by Dr. P. D. Lipscomb; *Some Reflections on Scientific Mechanotherapy, So Called Osteopathy*, by Dr. V. Ulrich. Among those who took part in the discussion were Dr. J. N. Upshur and Dr. J. Garnett Nelson.

**The Annual Report of the Library Committee of the College of Physicians of Philadelphia** for the year 1907 shows that there were 75,616 volumes in the library at the close of the year. There were also on the shelves 8,807 unbound reports and transactions; 21,733 theses and dissertations, and 62,300 unbound pamphlets. During the year 3,344 volumes, 17,138 pamphlets, 28,109 numbers of medical periodicals, and 800 inaugural dissertations were received.

**Association of American Physicians.**—The twenty-third annual meeting of this society will be held in the New Willard Hotel, Washington, D. C., on May 12th and 13th. The programme contains a long list of papers, and the meeting promises to be one of interest and value. The officers of the society are: President, Dr. James Tyson, of Philadelphia; vice president, Dr. Victor C. Vaughan, of Ann Arbor; secretary, Dr. Henry Hun, of Albany; treasurer, Dr. J. P. Crozer Griffith, of Philadelphia.

**Notice to Members of Tulane Alumni Association.**—All graduates of the medical department of Tulane University who intend to be present at the meeting of the American Medical Association in Chicago, on June 2d to 5th, are requested to write at once to Dr. Hugh B. Williams, 100 State street, Chicago, for information concerning the gathering of the alumni on June 2d. The headquarters for Tulane graduates will be at the Auditorium Hotel, and alumni are urged to call upon their arrival for information.

**Medical Association of Georgia.**—The fifty-ninth annual meeting of this society, which was held in Fitzgerald on April 15th, 16th, and 17th, was one of the most satisfactory in the history of the organization. Officers for the ensuing year were elected as follows: President, Dr. T. D. Coleman, of Augusta; first vice president, Dr. W. B. Armstrong, of Atlanta; second vice president, Dr. R. Lattimore, of Savannah; secretary and treasurer, Dr. Claude A. Smith, of Atlanta. Mason was selected as the place of meeting for 1909.

**The Medical Association of the Southwest.** This association, which embraces the states of Kansas, Arkansas, Oklahoma, Texas, and Missouri, will hold its next annual meeting in Kansas City, Mo., on October 20th and 21st. The secretary, Dr. F. H. Clark, of El Reno, Okla., is actively engaged in the preparation of an extensive programme, and the committee on arrangements is already making plans for the entertainment of those who attend. Dr. John Benton, 222 Albany Building, Kansas City, Mo., is chairman of the committee on arrangements, and will be glad to answer all inquiries relative to the meeting.

**Kansas Medical Society.**—The forty-second annual meeting of this society will be held at Elks Hall, Topeka, Kan., on May 6th, 7th, and 8th. A splendid programme has been prepared, and the meeting promises to be one of great interest. The officers of the society are: President, Dr. J. E. Sawtell, of Kansas City; vice presidents, Dr. Thomas Kirkpatrick, of Garnett; Dr. M. F. Jarrett, of Fort Scott, and Dr. George M. Gray, of Kansas City; secretary, Dr. Charles S. Huffman, of Columbus; and treasurer, Dr. L. H. Munn, of Topeka.

**The Canadian Hospital Association.**—At the annual meeting of this association, which was held in Toronto on April 21st, the following officers were elected for the ensuing year: President, Dr. W. J. Dobbie, of Weston; first vice president, Dr. A. D. MacIntyre, of Kingston; second vice president, H. E. Webster, of Montreal; third vice president, Miss I. C. Brent, of Toronto; fourth vice president, W. W. Kenny, of Halifax; fifth vice president, L. L. Cosgrove, of Winnipeg; secretary, Dr. J. N. E. Brown, of Toronto; treasurer, Miss Patten, of Toronto.

**The Society of Normal and Pathological Physiology, Philadelphia.**—A meeting of this society was held in the new medical laboratory of the University of Pennsylvania on Monday evening, April 27th. Dr. J. E. Sweet read a paper covering a report of the work accomplished in experimental surgery. Dr. D. W. Fetterolf read a paper dealing with the preliminary results of the analysis of diabetic foods. Dr. N. Gildersleeve read a paper entitled *Streptothrix Infections*. Dr. W. H. F. Addison read a paper on the Structure of the Cerebellar Cortex, and Dr. H. B. Wood read a paper on the Variability of the Parathyroid.

**A Dinner to Professor Schäfer, of Edinburgh.**—A dinner was given in honor of Professor E. A. Schäfer, F. R. S., of the University of Edinburgh, on the evening of April 22d, at the Shoreham Hotel, Washington, D. C. Among those present were President Buell, of Georgetown University; President Needham, of George Washington University; Dr. Barchfeld, Member of Congress; Surgeon General Wyman, United States Public Health and Marine Hospital Service; Dr. W. W. White, superintendent of the Government Hospital for the Insane; Professor Shields, of the Catholic University of America, and Professor Franz, of George Washington University.

**The Mississippi Valley Medical Association.**—The thirty-fourth annual meeting of this society will be held in Louisville, Ky., on October 13th, 14th, and 15th. Announcement has just been made that Dr. George Dock, professor of medicine in the University of Michigan, Ann Arbor, will deliver the address in medicine, and Dr. Arthur Dean Bevan, professor of surgery in Rush Medical College, Chicago, will deliver the address in surgery. The officers of the society are as follows: President, Dr. Arthur R. Elliott, of Chicago; first vice president, Dr. Florus F. Lawrence, of Columbus, Ohio; second vice president, Dr. Robert C. McChord, of Lebanon, Ky.; secretary, Dr. Henry Enos Tully, of Louisville, Ky.; treasurer, Dr. S. C. Stanton, of Chicago; chairman of the Committee on Arrangements, Dr. Louis Frank, of Louisville, Ky.

**Scientific Society Meetings in Philadelphia for the Week Ending May 9, 1908.**—*Monday, May 5th*, Philadelphia Academy of Surgery; Biological and Microscopical Section, Academy of Natural Sciences; West Philadelphia Medical Association; Northwestern Medical Society. *Tuesday, May 5th*, Academy of Natural Sciences. *Wednesday, May 6th*, College of Physicians; Association of Clinical Assistants; Johns Hospital. *Thursday, May 7th*, American Therapeutical Society; Obstetrical Society; Medical Society of the Southern Dispensary; Section Meeting, Franklin Institute; Germantown Branch, Philadelphia County Medical Society. *Friday, May 8th*, American Therapeutical Society; Northern Medical Association; West Branch, Philadelphia County Medical Society. *Saturday, May 9th*, American Therapeutical Society.

**The Health of Philadelphia.**—During the week ending April 11, 1908, the following cases of transmissible diseases were reported to the Bureau of Health of Philadelphia: Typhoid fever, 68 cases, 15 deaths; scarlet fever, 76 cases, 0 deaths; chickenpox, 34 cases, 0 deaths; diphtheria, 75 cases, 14 deaths; cerebrospinal meningitis, 5 cases, 2 deaths; measles, 244 cases, 2 deaths; whooping cough, 12 cases, 0 deaths; pulmonary tuberculosis, 109 cases, 62

deaths; pneumonia, 73 cases, 64 deaths; erysipelas, 7 cases, 1 death; puerperal fever, 2 cases, 5 deaths; anthrax, 1 case, 1 death; mumps, 37 cases, 0 deaths; cancer, 20 cases, 23 deaths. The following deaths were reported from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 9 cases; diarrhoea and enteritis, under two years of age, 11 cases. The total deaths numbered 534 in an estimated population of 1,532,738, corresponding to an annual death rate of 18.10 in 1,000 of population. The total infant mortality was 123; under one year of age, 96; between one and two years of age, 27. There were 52 still births; 35 males, and 17 females.

#### Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Department of Health for the following statement of new cases and deaths reported for the two weeks ending April 25, 1908:

	—April 18.—		—April 25.—	
	Cases.	Deaths.	Cases.	Deaths.
Tuberculosis pulmonalis	444	189	439	180
Diphtheria	430	31	344	39
Measles	1,649	49	1,891	39
Scarlet fever	1,005	69	929	64
Smallpox	2	..	..	..
Variella	138	..	153	..
Typhoid fever	19	5	33	11
Whooping cough	13	3	14	1
Cerebrospinal meningitis	7	7	12	3
Totals	3,674	397	3,815	341

**The Mortality of Chicago.**—According to the weekly bulletin of the Department of Health, during the week ending April 11th there were 600 deaths from all causes, as compared with 717 for the corresponding period in 1907. The annual death rate in 1,000 of population was 14.44. Of the total number of deaths, 344 were of males and 256 of females. Under one year of age, 143; between one and five years of age, 44; between five and twenty years of age, 21; between twenty and sixty years of age, 251; over sixty years of age, 141. The principal causes of death were: Apoplexy, 5; Bright's disease, 36; bronchitis, 19; consumption, 69; cancer, 28; convulsions, 3; diphtheria, 1; heart diseases, 58; influenza, 5; intestinal diseases, acute, 39; measles, 4; nervous diseases, 18; pneumonia, 97; scarlet fever, 5; suicide, 13; typhoid fever, 4; violence other than suicide, 23; whooping cough, 3; all other causes, 170.

**Montgomery County, Md., Medical Association.**—The annual meeting of this association was held in Rockville on Tuesday, April 21st. Dr. James E. Deets, of Clarksburg, the retiring president, presided, and Dr. John L. Lewis, of Bethesda, acted as secretary. A committee, consisting of Dr. J. W. Chappell, of Tenleytown, Dr. Otis M. Linthicum, of Rockville, and Dr. Horace P. Haddox, of Gaithersburg, was appointed by the association to consider the feasibility of establishing a hospital in the county, to be under the control of the association, and to devise ways and means of financing the project. The principal feature of the scientific programme was an address on tuberculosis by Surgeon General Sternburg, of the United States Army. An election of officers was held, which resulted as follows: President, Dr. Charles Farquhar, of Olney; vice president, Dr. Otis Linthicum, of Rockville; secretary and treasurer, Dr. John L. Lewis, of Bethesda.

**Personal.**—Dr. G. M. F. Rogers, of Minneapolis, Minn.; Dr. M. J. Lilly, of Switchback, W. Va.; Dr. Edward D. Helfrich, of Galion, Ohio; and Dr. Elbin J. Johnson, of Wind Ridge, Pa., are registered at the Philadelphia Polyclinic and College for Graduates in Medicine.

Dr. J. Henry Carstens, of Detroit, has announced that he will accept the Republican nomination for mayor.

Dr. Charles E. Donlan has been elected superintendent of the Boston almshouse and hospital on Long Island.

Dr. Herbert B. Howard, of Boston, has resigned his position as resident physician of the Massachusetts General Hospital, to become head of the new Peter Brigham Hospital in Brookline.

Dr. L. M. Early, of Columbus, Ohio, has had his left hand amputated as a result of x-ray burns.

Dr. William G. McCallum, resident pathologist of the Johns Hopkins Hospital, has been appointed head of the pathological department of the City Hospital, Cincinnati, and of the Cincinnati University.

Dr. Frederick A. Hunt, of Jamesville, N. Y., has been appointed physician to the Oneida County Penitentiary.

**Vital Statistics of New York.**—According to the report of the Department of Health of the City of New York for the week ending April 18th, there were during the week 1,544 deaths from all causes, corresponding to an annual death rate of 18.21 in 1,000 of population. Of the total number of deaths 801 were in the Borough of Manhattan, 177 in the Borough of the Bronx, 404 in Brooklyn, 56 in Queens, and 16 in Richmond. The Borough of the Bronx had a death rate of 28.19, which was the highest for the five boroughs, but the death rate of this borough is increased by the presence of several large institutions, the inmates of which are residents of the other boroughs. There were 2,142 births, 387 marriages, and 127 still births reported for the week.

**American Pharmaceutical Association.**—The Philadelphia branch of this society will hold a stated meeting in the College of Physicians on the evening of Tuesday, May 5th, at 8 o'clock. The program for the evening includes a discussion of pharmaceutical associations and their uses, and physicians are invited to give suggestions or offer criticism of the work that is now being done in connection with the several pharmaceutical organizations. Many pharmacists appreciate that there is a need for active, energetic work to advance the science of pharmacy in this country, and are earnestly endeavoring to bring about a reawakening on the part of others engaged in the same calling. The discussion will be opened by the following contributions: The N. A. R. D. as a Factor in the Progress of Pharmacy, by Mr. Thomas H. Potts; The Status of Pharmacy and of Pharmacists in Europe, by Mr. M. I. Wilbert; The Reorganization of the American Pharmaceutical Association, by Professor Henry Kraemer.

#### Society Meetings for the Coming Week:

**MONDAY, May 4th.**—German Medical Society of the City of New York; Utica, N. Y., Medical Library Association; Niagara Falls, N. Y., Academy of Medicine (annual); Practitioners' Club, Newark, N. J. (annual); Hartford, Conn., Medical Society.

**TUESDAY, May 5th.**—New York Academy of Medicine (Section in Dermatology); New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Hudson County, N. J., Medical Association (Jersey City) (annual); Medical Association of Troy and Vicinity, N. Y.; Hornellsville, N. Y., Medical and Surgical Association; Long Island, N. Y., Medical Society; Bridgeport, Conn., Medical Association.

**WEDNESDAY, May 6th.**—Psychiatric Society of New York; Society of Alumni of Bellevue Hospital, New York; Harlem Medical Association, New York; Elmira, N. Y., Academy of Medicine.

**THURSDAY, May 7th.**—New York Academy of Medicine; Danville, N. Y., Medical Association.

**FRIDAY, May 8th.**—New York Society of Dermatology and Genitourinary Surgery; New York Academy of Medicine (Section in Otolaryngology); Eastern Medical Society of the City of New York; Saratoga Springs, N. Y., Medical Society.

**SATURDAY, May 9th.**—Therapeutic Club, New York.

**Philadelphia Bureau of Health Statistics.**—During the month of February, 1908, in the Division of Medical Inspection 1,720 inspections were made, excluding schools, 601 fumigations were ordered, 38 cases were ordered for special diagnosis, 3,001 visits were made to schools, and 767 children were excluded from school, 420 cultures were taken, 160 injections of antitoxine were given; and 233 persons were vaccinated. In the Division of Vital Statistics 2,373 deaths, 3,175 births, and 271 marriages were recorded. In the Division of Milk Inspection 7,183 inspections were made of 160,798 quarts of milk, of which 450 quarts were condemned. Six persons were examined chemically and 841 microscopically. In the Division of Meat and Cattle Inspection 3,605 inspections were made, 84 showed unsatisfactory features, and 214 carcasses were condemned. 893 post mortem examinations were made, with 44 condemnations. In the Division of Disinfection a fumigation was ordered for mumps, 270 for scarlet fever, 430 for diphtheria, 106 for typhoid fever, 215 for tuberculosis, and 146 for miscellaneous diseases. Twenty eight schools were disinfected. In the Bacteriological Laboratory 1,005 cultures were examined for the presence of bacilli typhi-

theria; 431 specimens of blood were examined for the serum diagnosis of typhoid fever; 841 specimens of milk and 180 specimens of sputum were examined; 6 disinfection tests were made; and 3,913,850 units of antitoxine were distributed. In the Clinical Laboratory 98 analyses were made.

#### Meetings of State Medical Societies for the Month of May, 1908:

Arkansas Medical Society, annual meeting at Little Rock, May 13th, 14th, and 15th.

Connecticut Medical Society, annual meeting at New Haven, May 27th and 28th.

Illinois State Medical Society, annual meeting at Peoria, May 19th, 20th, and 21st.

Indiana State Medical Association, annual meeting at French Lick, May 23d, 24th, and 25th.

Iowa State Medical Society, annual meeting at Des Moines, May 20th, 21st, and 22d.

Kansas Medical Society, annual meeting at Iola, May 6th, 7th, and 8th.

Missouri State Medical Association, annual meeting at Sedalia. Date not announced.

Montana State Medical Association, annual meeting at Butte, May 13th and 14th.

New Hampshire Medical Society, annual meeting at Concord, May 14th and 15th.

Nebraska State Medical Association, annual meeting at Lincoln, May 5th, 6th, and 7th.

Medical Society of the State of North Carolina, annual meeting at Winston Salem, May 25th.

North Dakota Medical Association, annual meeting at Grand Forks, May 20th and 21st.

Ohio State Medical Association, annual meeting at Columbus, May 6th, 7th, and 8th.

Oklahoma State Medical Association, annual meeting at Sulphur, May 14th, 15th, and 16th.

The State Medical Association of Texas, annual meeting at Corpus Christi, May 12th.

Utah State Medical Association, annual meeting at Salt Lake, May 12th and 13th.

**The Fifth Pan-American Medical Congress.**—The executive committee of this congress, which will be held in Guatemala City, Guatemala, on August 5 to 10, 1908, announce the following list of subjects for the general discussions: General Medicine—Tropical Anemias; The Present Cause and Treatment of Cancer. Surgery—Prostatectomy; Operations for Repairing the Ureters. Hygiene and Demography—Should the Segregation of Lepers be Enforced? Demographic Distribution of Tuberculosis in America. Mental and Nervous Diseases—Classification of Mental Diseases; A Discussion of Dementia Praecox. Internal Medicine—Tropical Diseases The Character and Causes of Which Have Not Yet Been Determined; Ankylostoma. Gynecology—Can Metritis be Considered as a Predisposing Cause of Cancer of the Uterus? The Best Means of Keeping the Uterus in Position in Cases of Prolapse. Military Sanitation—First Aid to the Injured on the Battlefield and the Organization of an Advance Guard to Render Assistance; The Hygienic Equipment of the Soldier. Syphilis and Dermatology—Parasites and the Locomotor Ataxia Syphilitic. Ophthalmology—What is the Best Method of Treating Pigmentary Retinitis That We Have at Present? Discussion of Trachoma. Otitis. Post Partum Hemorrhage in Aclimatic Lesions of the Heart. Children's Diseases—Infantile Meningitis. Medical and Psychological Causes That Attenuate or Annul the Responsibility; Civil Rights Relative to People's Mental Condition. Laryngology and Rhinology—Causes and Treatment of Rhinoscleroma. Dental Surgery—Indications for the Extraction of Teeth. Radiography—Examination Methods Used in Radiography. Bacteriology—Bacteriological Study of Typhus Fever; Bacteriological Study of Rhinoscleroma. Bacteriological Study of Leprosy. Filaria Sanguinis Humani in Central America; Diseases That Can Be Transmitted by Mosquito Bites. Maternal Medicine. General American Quinine. Central American Sarsaparilla. A Study of the Mexican Periodic. Etc. Those who desire to present papers on any of these subjects, or to take part in the discussion, should send their names at once either to Dr. Virilio Gonzalez Secretario, Guatemala, or to Dr. Ramon Gomez, American Society, 78 West Fifth Street, New York.

# THE BOOKS OF SIX MONTHS

## THE PRINCIPAL MEDICAL BOOKS PUBLISHED SINCE OCTOBER 1, 1907

Nearly all the medical books that have been issued by American publishers during the year, as well as many others of foreign production, have already been reviewed in our columns. These reviews, however, are scattered throughout the different numbers of the Journal for the entire year, and are consequently not easily accessible to the reader. We feel confident, therefore, that our readers will find that the list which we have compiled here below will be of great value as a guide to the selection of books for the library. In view of the fact that the majority of the books have already received review notice, we insert only occasional brief comments. For convenience of reference, the titles of the publishing houses are arranged alphabetically.

### ENGLISH.

#### D. APPLETON & COMPANY, New York.

ANDERS.—*A Textbook of Physical Diagnosis.* By HOWARD S. ANDERS, A. M., M. D., Medico-Chirurgical College, Philadelphia. 8vo. Illustrated. Price, cloth, \$3 net.

Its simplicity and excellent scheme bring out the essential features of diagnosis and furnish all material desirable for a student previous to clinical experience.

BABCOCK.—*Diseases of the Heart and Arterial System.* By ROBERT H. BABCOCK, A. M., M. D., Chicago. Second Edition, Revised, with 3 Colored Plates and 139 Illustrations. 8vo. Price, cloth, \$6 net.

BABCOCK.—*Diseases of the Lungs.* By ROBERT H. BABCOCK, A. M., M. D. A companion volume to Diseases of the Heart and Arterial System. With 11 Colored Plates and 104 Illustrations. 8vo. Price, cloth, \$6 net.

BAUMANN.—*Gonorrhœa, Its Diagnosis and Treatment.* By FREDERICK BAUMANN, Ph. D., M. D., College of Physicians and Surgeons, Chicago.

This little book is especially valuable in omitting many well known details, and giving clearly and concisely the essential points in the diagnosis and treatment of gonorrhœa and its surgical sequelæ.

CHURCH.—*Diseases of the Nervous System.* The fourth volume of *Modern Clinical Medicine*, Edited by ARCHIBALD CHURCH, M. D., Northwestern University, Chicago.

This book is characterized by a thoroughness and comprehensiveness typical of German productions, and will be found of the highest service to students and practitioners.

FOOTE.—*Minor Surgery.* By EDWARD MILTON FOOTE, A. M., M. D., College of Physicians and Surgeons, Columbia University, New York. 407 Illustrations. Price, cloth, \$5, net.

This book treats of the every day operations of surgical practice, those problems in surgery which are not adequately discussed in the works which take cognizance of the more serious conditions.

HOLT.—*The Diseases of Infancy and Childhood.* By L. EMMETT HOLT, M. D., Sc. D., LL. D., College of Physicians and Surgeons, Columbia University, New York. Third Edition, Revised and Enlarged. With 245 Illustrations, including 8 Colored Plates. Price, cloth, \$6 net.

KELLY.—*New Medical Gynecology.* By HOWARD A. KELLY, M. D., Johns Hopkins Hospital, Baltimore, Md. Over 100 Original Illustrations. Price, cloth, \$6 net.

A work of great importance, which, taken with Kelly's *Operative Gynecology*, gives you a complete treatise on the best authority.

Price.—*The Principles and Practice of Parasitology.* By

Illustrations in the Text and one Colored Plate. 8vo. Price, cloth, \$6 net.

That the work is thoroughly up to date is evinced by the description of meralgia paræsthetica and uncinariasis of the skin and by the discussion on the *Spirochæta pallida* and on Wright's method of treatment.

WILLIAMS.—*Obstetrics.* By J. WHITRIDGE WILLIAMS, Johns Hopkins University, Baltimore, Md. 8vo. 820 pages. 630 Illustrations, 8 Colored Plates. Price, cloth, \$6 net.

This book is written in a clear and admirable manner, it is comprehensive and exact, and last, but not least, it is written in English.

WYNTER.—*Minor Medicine.* By WALTER ESSEX WYNTER, M. D., B. S., London. Price, cloth, \$2 net.

This book is a treatment on the simpler disorders, such as bilious attack, dyspepsia, stye, epistaxis, neuralgia, chilblains, heartburn, constipation, corn cures, syncope, cough, toothache, hiccup, baldness, cephalalgia, seasickness, warts, enuresis, cold in the head, etc.

#### P. BLAKISTON'S SON & COMPANY, Philadelphia.

ALLEN.—*The Opsonic Method of Treatment.* By Dr. RICHARD W. ALLEN, A. M., M. B., Pathologist, Royal Eye Hospital, London, etc. 8vo, Containing 16 Charts. Price, cloth, \$1.50 net.

An opportune book that has aroused so much interest that two importations were exhausted immediately upon their receipt in this country.

BARTLEY.—*Physiological and Clinical Chemistry.* The Chemical Examination of the Saliva, Gastric Juice, Fæces, Milk, Urine, etc., with Notes on Urinary Diagnosis, Volumetric Analysis, and Weights and Measures. By E. H. BARTLEY, M. D., Professor of Chemistry, Toxicology, and Pediatrics in the Long Island College Hospital, late Dean and Professor of Chemistry, Brooklyn College of Pharmacy, etc. Third Edition. With 51 Illustrations. 12mo. 202 pages. Cloth, \$1 net.

CUFF.—*Lectures on Medicine to Nurses.* By HERBERT E. CUFF, M. D., F. R. C. S., Late Medical Superintendent, Northern Fever Hospital, Tottenham, London. Fifth Edition. Illustrated. 12mo. 269 pages. Cloth, \$1.25 net.

DANIELS.—*Laboratory Studies in Tropical Medicine.* By C. W. DANIELS, M. R. C. S., Late Medical Superintendent of the London School of Tropical Medicine, etc. With 4 Colored Plates, Containing 92 Figures, 6 Charts, and 156 other Illustrations. 8vo. Price, cloth, 4 net.

Intended to serve as a guide for physicians engaged in scientific medical work in tropical countries

[illegible]

KREISSL. *A Treatise on the Practical Treatment of Diseases of the Urinary and Genital Systems.* By FILIP KREISSL, M. D., Professor of Genitourinary Diseases in the Chicago Clinical School, late Attending Surgeon to Cook County Hospital. 500 pages. About 200 illustrations. Price, \$5; half morocco, \$6.

LEVINGS. *Everyday Surgery.* A Practical Guidebook on Everyday Surgery and Surgical Handicraft. By A. HAMILTON LEVINGS, M. D., Professor of the Principles and Practice of Surgery in the Wisconsin College of Physicians and Surgeons; Surgeon to St. Joseph's, Milwaukee County, and Mt. Sinai Hospitals; Consulting Surgeon to Johnston's Emergency Hospital and to the Milwaukee County Hospitals for the Acute and Chronic Insane. Over 900 pages. 500 Illustrations. Price, cloth, \$5; half morocco, \$6.

OCHSNER AND STURM. *The Organization, Construction, and Management of Hospitals.* With Numerous Plans and Details. By ALBERT J. OCHSNER, B. S., F. R. M. S., M. D., Surgeon in Chief, Augustana Hospital, and Professor of Clinical Surgery, Medical Department University of Illinois. And MEYER J. STURM, B. S., Architect, Chicago. 600 pages. About 350 Illustrations. Price, cloth, \$7; half morocco, \$8.

PATTON. *Anesthesia and Anæsthetics, General and Local.* For Practitioners and Students of Medicine and Dentistry. By JOSEPH M. PATTON, M. D., Professor of Internal Medicine, Chicago Policlinic; Clinical Professor of Diseases of the Chest, Medical Department University of Illinois. Over 200 pages. 60 Illustrations. Price, cloth, \$2.50.

### THE CLINIC PUBLISHING COMPANY, Chicago.

CANDLER. *The Every Day Diseases of Children and Their Proper Treatment.* Pertinent Points on Pediatrics; Diseases of the Newborn; Diseases of the Nose, Throat, Mouth, and Ear; Diseases of Nutrition; Diseases of the Stomach and Bowels; Diseases of the Liver; Diseases of the Urogenital System; the Acute Infectious Diseases; Diseases of the Nervous System, etc. By GEO. H. CANDLER, M. D., Chicago. 386 pages. Price, cloth, \$1.

LANPHEAR. *Surgical Therapeutics.* Practical Suggestions for the Management of Surgical Cases, Management of Fractures, and Dislocations; Application of Bandages, Dressings, and Compress Preparations in the Use of Anæsthetics; Preparation of Patients for Operation and Postoperative Treatment; also the Medicinal Treatment of the Surgical Diseases. By EMORY LANPHEAR, M. D., LL. D., St. Louis, Mo. 396 pages. Price, cloth, \$1.

### THE GRAFTON PRESS, New York.

RAVOGLI. *Syphilis. In its Medical, Medicolegal and Sociological Aspects.* By A. RAVOGLI, M. D., Professor of Dermatology and Syphilology at the Medical College of Ohio, Medical Department of Cincinnati University. Octavo, about 520 pages. 21 Illustrations. Price, cloth, \$5 net; carriage extra.

### THE ILLUSTRATED MEDICAL JOURNAL COMPANY, Detroit.

LEONARD. *Physicians' Office Day Book.* By C. HENRI LEONARD, M. D. Size, 6x9 inches, 136 pages. Leather and cloth binding. 1 Volume. Good for twenty-five families daily for four years; for fifty families daily for two years. Price, \$2.

LEONARD. *Physicians' Handy Ledger.* By C. HENRI LEONARD, M. D. Size, 7x10 inches, 250 pages. Leather and cloth binding. Good for four hundred families yearly for five years. Price, \$2.50.

### WILLIAM R. JENKINS COMPANY, New York.

WINSLOW. *Production and Handling of Clean Milk.* A complete, plain, practical, and authoritative guide to the production and distribution of clean milk for farmers, health officers, milk inspectors, students of agriculture and dairying country gentlemen, physicians, and others interested in matters pertaining to dairying and hygiene. By KENELM WINSLOW, M. D., M. D. V., B. A. S. (Harv.), formerly Instructor in Bussey Agricultural Institute and Assistant Professor in the Veterinary School of Harvard University. Size, 6¼x9¾, 207 pages, many illustrations, including 1 colored and 15 full-page plates. Price, cloth, \$2.50.

### W. T. KEENER & COMPANY, Chicago.

BALLANTYNE.—Seven Volumes of the *Encyclopædia and Dictionary of Medicine and Surgery and the Specialties.* By the Most Eminent Authorities. Edited by J. W. Ballantyne. In Ten Volumes. Price, \$5 a volume.

BLAND-SUTTON.—*Tumors, Innocent and Malignant. Their Clinical Characters and Appropriate Treatment.* By J. BLAND-SUTTON, F. R. C. S. Fourth Edition. With 355 Engravings. 675 Illustrations. Price, cloth, \$5 net.

BOWLEY.—*Surgical Pathology and Morbid Anatomy.* By ANTHONY A. BOWLEY, C. M. G., F. R. C. S. Fifth Edition. Edited with the Assistance of Dr. F. W. ANDREWS. 632 pages. Price, cloth, \$3.50 net.

BUCHANAN.—*Manual of Anatomy, Systematic and Practical, Including Embryology.* By A. M. BUCHANAN, M. A., M. D., C. M., F. R. P. S. (Glas.). Two Volumes. With 268 Illustrations, Mostly Original and in Colors. Price, \$2.75 a volume.

CRIPPS.—*On Diseases of the Rectum and Anus.* Including the Fifth Edition of the Jacksonian Prize Essay on Cancer. By HARRISON CRIPPS, F. R. C. S. Third Edition. 538 Pages. Price, cloth, \$4 net.

EDEN.—*Manual of Midwifery.* By THOMAS WATTS EDEN, M. D., C. M. (Edin.), F. R. C. P. (Lond.). With 26 Plates and 233 Illustrations in the Text. 518 pages. Price, cloth, \$3.50 net.

FRENCH.—*Medical Laboratory Methods and Tests.* By HERBERT FRENCH, M. A., M. D. (Oxon.), F. R. C. P. (Lond.). Second Edition. 175 pages. Price, \$1.50 net.

GRIMSDALE.—*Textbook of Ophthalmic Operations.* By HAROLD GRIMSDALE, M. B., F. R. C. S., and ELMORE BREWERTON, F. R. C. S. 349 pages. Price, cloth, \$4.50 net.

HARRIS.—*Electrical Treatment.* By WILFRED HARRIS, M.D. (Cantab.), F. R. C. P. (Lond.) Illustrated. 372 pages. Price, \$2.25 net.

LAVERAN AND MESNIL. *Trypanosomes and Trypanosomiasis.* By A. LAVERAN and F. MESNIL. Translated and Much Enlarged by DAVID NAVARRO, M. D., B. Sc., D. P. H. (London). With Colored Plates and 81 Figures in the Text. 538 pages. Price, cloth, \$7.50 net.

METCHNIKOFF AND LANKESTER.—*The New Hygiene. Three Lectures on the Prevention of Infectious Diseases.* By ELIE METCHNIKOFF. With a Preface by E. RAY LANKESTER. 104 pages. Price, \$1.

MORRIS AND DORE.—*Light and X Ray Treatment of Skin Diseases.* By MALCOLM MORRIS, F. R. C. S. (Ed.), and S. ERNEST DORE, M. D. (Cantab.). With 12 Plates. 172 pages. Price, \$1.50 net.

PAGE.—*Elements of Physics for Medical Students.* By FREDERIC JAMES M. PAGE, B. Sc. (Lond.), F. I. C., Associate of the Royal School of Mines. With a Colored Frontispiece and 230 Figures in the Text. 288 pages. Price, \$1.25 net.

PATON.—*Essentials of Physiology for Veterinary Students.* By D. NOEL PATON, M. D., B. Sc., F. R. C. P. (Edin.). Second Edition. Revised and Enlarged. 404 pages. Price, cloth, \$3 net.

ROBERTSON.—*Meat and Food Inspection*. By WILLIAM ROBERTSON, M. D., D. P. H. F. P. S. With *Regulations Governing Meat Inspection in the United States*. By MAXIMILIAN HEZOG, M. D. 8vo. Illustrated. Price, cloth, \$3.50 net.

SAVAGE AND GOODALL.—*Insanity and Allied Neuroses. A Practical and Clinical Manual*. By GEORGE H. SAVAGE, M. D., F. R. C. P. With the Assistance of EDWIN GOODALL, M. D. (Lond.), B. S., F. R. C. P. With 9 Colored Plates and 45 Illustrations in the Text. New and Enlarged Edition. 624 pages. Price, cloth, \$2.75 net.

STARLING.—*Meiners' Company Lectures on Recent Advances in the Physiology of Digestion*. Delivered in the Michaelmas Term, 1905, in the Physiological Department of University College, London. By ERNEST H. STARLING, M. D., F. R. S. With 12 Illustrations. 156 pages. Price, cloth, \$2 net.

VON NOORDEN.—*Metabolism. The Physiology and Pathology of Metabolism, With its Applications to Practical Medicine*. By CARL VON NOORDEN. In Three Volumes. 1500 pages. Royal 8vo. Price, cloth, \$16 a set.

WALSH.—*The Hair and Its Diseases, Including Ringworm, Greyness and Baldness. An Introductory Handbook*. By DAVID WALSH, M. D. (Edin.). Second Edition. 94 pages. Price, \$1 net.

WOOD AND WOODRUFF.—*The Commoner Diseases of the Eye. How to Detect and How to Treat Them*. For Students of Medicine. With 280 Illustrations (Many Original) and 8 Colored Plates. By CASEY A. WOOD, C. M., D. C. L., and THOMAS A. WOODRUFF, M. D., C. M., L. R. C. P. (London). Third Edition, Enlarged and Improved, with Index. 508 pages. Price, \$2.50 net.

### LEA & FEBIGER, Philadelphia.

ADAMI.—*A Treatise on General Pathology*. By J. GEORGE ADAMI, M. D., Professor of Pathology in McGill University, Montreal. In one handsome octavo volume of about 850 pages, with 265 engravings and 9 colored plates.

A correct grasp of pathology, the actual phenomena of disease conceived as an entity, must underlie its recognition or diagnosis, and hence also its rational treatment. In this new work one of the world's masters of the subject will develop the general aspects with well rounded knowledge and in clear and charming literary style. The volume will equally answer the needs of students and practitioners.

BALLENGER.—*A Treatise on Diseases of the Nose, Throat and Ear*. By WILLIAM LINGEN BALLENGER, M. D., Professor of Laryngology, Rhinology, and Otology in the College of Physicians and Surgeons, Chicago. Octavo, about 1,000 pages with about 500 original engravings and 9 colored plates.

This new work by a leading American authority will cover both the medical and surgical aspects of diseases of the nose, throat, and ear. The skill of the accomplished teacher is manifest in the clear and sequential presentation of each subject. The book will be particularly notable for its profuse series of illustrations, which are entirely original and specially drawn to emphasize important points, often being in series in order to give the successive steps of operative procedures.

DEARBORN.—*A Treatise on Diseases of the Students of Practitioners*. By GEORGE V. N. DEARBORN, M. D. (Harvard), Professor of Physiology in Tufts Medical College. Pocket Octavo, 300 pages, with about 400 engravings and 8 colored plates.

In a volume of moderate size Professor Dearborn has succinctly covered the field of modern physiology. He has, moreover, indicated its relations to

other departments of medicine. He has accordingly produced an excellent textbook for students and a useful work of reference for practitioners. The abundant engravings and plates are pertinent and instructive.

EGBERT.—*A Manual of Hygiene and Sanitation*. By SENECA EGBERT, M. D., Professor of Hygiene in the Medico-Chirurgical College, Philadelphia. Fourth edition, thoroughly revised. 12mo., 498 pages, with 93 illustrations. Price, cloth, \$2.25, net.

HARDWAY AND GRINDON.—*A Handbook of Cutaneous Therapeutics*. By W. A. HARDWAY, A. M., M. D., Professor of Diseases of the Skin and Syphilis, and JOSEPH GRINDON, Ph. B., M. D., Professor of Clinical Dermatology and Syphilis, in the Washington University, St. Louis. 12mo., 608 pages. Price, cloth, \$2.75, net.

By concentrating attention upon diagnosis and treatment the two eminent authors have been able to cover the whole practical side of dermatology in an exceedingly comprehensive volume of moderate size. They have written for the general practitioner, who must treat a class of cases often considered difficult and obstinate. The therapeutic sections are abundant and place at the reader's command means and methods easily accessible. At the end of many of the chapters are given carefully selected formulas in addition to those in the text. The foregoing characteristics will also render the volume particularly suitable as a textbook in the majority of college courses.

HARE.—*A Textbook of Practical Diagnosis. The Use of Symptoms in the Diagnosis of Disease*. By HOBART AMORY HARE, M. D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia. New (6th) edition, thoroughly revised. Octavo, 616 pages, with 203 engravings and 16 full-page colored plates. Price, cloth, \$4.50 net.

OSLER.—*Modern Medicine. Its Theory and Practice in Original Contributions by Eminent American and Foreign Authors*. Edited by WILLIAM OSLER, M. D., Regius Professor of Medicine in Oxford University, England; Honorary Professor of Medicine in Johns Hopkins University, Baltimore; formerly Professor in the University of Pennsylvania, Philadelphia, and in McGill University, Montreal. Assisted by THOMAS MCCRAE, M. D., Associate Professor of Medicine and Clinical Therapeutics in the Johns Hopkins University, Baltimore. In seven octavo volumes of about 900 pages each, illustrated. Price, per volume, cloth, \$6, net; leather, \$7, net; half morocco, \$7.50, net. Subscriptions received only for the whole work.

The value of such a work, or, rather, the necessity for it at the present time, scarcely needs to be stated. Of all the professions, that which grapples with the problems of life and death most requires the fullest knowledge which can be developed by human effort and experience. Responding to this need, medicine is the most active and fruitful of all professions in developing new knowledge. As one advance begets another, progress is self accelerating. The past century was more productive than all prior time, and years now outstrip former decades. Complete presentations of medicine therefore become necessary at more frequent intervals, and render a double service by placing every member of the profession in command of the best collective knowledge of all, and providing a new and higher plane for fresh advances. The one requisite is that such works shall be authoritative and applicable to practical ends. They must start under such auspices as will attract the real leaders in the various subjects to present their knowledge, the right man must be chosen for each, and the assembled parts must cover the whole

realm. Only the broadest mind can view so vast a field in its natural perspective, neither magnifying nor neglecting anything. Only a man of the widest knowledge and universally admitted eminence can select the best writer for each chapter, whether in America, Europe, or Asia, and secure his cooperation. Dr. Osler combines all these requirements of knowledge and position, and so is thoroughly fitted to plan and edit such a work. The test of its value is its acceptance by the profession for use in their daily duties.

**PARK.**—*The Principles and Practice of Modern Surgery.* By ROSWELL PARK, M. D., Professor of Surgery in the University of Buffalo. In one very handsome imperial octavo volume of 1074 pages, with 722 engravings, and 60 full-page plates in colors and monochrome. Price, cloth, \$7, net; leather, \$8, net.

This new work from the individual pen of Dr. Park furnishes an authoritative and comprehensive exposition of the most modern surgery, both in its principles and practice. By the adoption of a large form the equivalent of fifteen hundred ordinary pages has been brought into a convenient volume of a thousand. It is a book of the widest utility and importance to all classes of readers concerned in any way with surgery. It suffices the student during his entire course by carrying him from the basic principles through to the diagnosis and operative treatment of all surgical affections. The consecutiveness and completeness of such a volume will appeal to teachers as an advantage second only to the clear presentation resulting from the author's long experience as a teacher himself. Practitioners requiring a guide thoroughly abreast of the times and answering all needs will appreciate the mature and conservative knowledge of one of the world's foremost surgeons. The author's surgical confrères will find much of interest and value in its pages.

**PORTS.**—*Nervous and Mental Diseases. A Manual for Students and Practitioners.* By CHARLES S. PORTS, M. D., Professor of Neurology in the Medico-Chirurgical College of Philadelphia. New (second) edition, thoroughly revised and greatly enlarged. In one 12mo volume of about 550 pages, with 133 engravings and 9 full-page plates.

**RUDDIMAN.**—*A Manual of Materia Medica.* For Students of Pharmacy. By E. A. RUDDIMAN, Ph. M., M. D., Professor of Pharmacy and Materia Medica in Vanderbilt University. 12mo, 453 pages. Price, cloth, \$2.25 net.

This textbook, written by an eminent teacher, succinctly covers one of the three main departments of the pharmaceutical curriculum, pharmacognosy, the knowledge of drugs, including their origin, description, properties, and uses. It is clear, systematic, and thorough.

**SIMON.**—*A Textbook of Physiological Chemistry.* For Students of Medicine and Physicians. By CHARLES E. SIMON, M. D., Professor of Clinical Pathology in the Baltimore Medical College; author of *Simon's Clinical Diagnosis*, etc. Octavo, 490 pages. Price, cloth, \$3.25 net.

**TREVES.**—*Surgical Applied Anatomy.* By SIR FREDERICK TREVES, F. R. C. S., Sergeant Surgeon to H. M. the King, formerly Lecturer on Anatomy at the London Hospital. New (fifth) edition. Revised by the Author, with the assistance of ARTHUR KEITH, M. D., F. R. C. S. 12mo, 640 pages, with 107 illustrations, of which 41 are in Color. Price, cloth, \$2.25 net.

**TREVES.**—*A Manual of Operative Surgery.* By SIR FREDERICK TREVES, F. R. C. S., Sergeant Surgeon to H. M. the King, Consulting Surgeon to the London Hospital

New edition, revised by the author and JONATHAN HUTCHINSON, JR., F. R. C. S., Surgeon to the London Hospital. In two octavo volumes.

## J. B. LIPPINCOTT COMPANY, Philadelphia.

**DE GARMO.**—*Abdominal Hernia.* By W. B. DE GARMO, M. D. Over 226 Illustrations. 8vo. 456 pages. Price, cloth, \$5 net. By subscription only.

**DWIGHT.**—*Variations of the Bones of the Hands and Feet.* By THOMAS DWIGHT, M. D., LL. D. Illustrations and Plates. 8vo. 108 pages. Price, cloth, \$5 net. By subscription only.

**FUCHS AND DIANE.**—*Textbook of Ophthalmology.* By ERNST FUCHS, Professor of Ophthalmology in the University of Vienna. Translated and Enlarged by ALEXANDER DUANE, M. D., Surgeon to Ophthalmic and Aural Institute, New York. 441 Illustrations in Colors and in Black and White. Third Edition. 8vo. 877 pages. Price, cloth, \$6 net. By subscription only.

**HARVEY Lectures.** Second Series. Lectures Delivered Under the Auspices of the Harvey Society of New York, 1906-1907. Illustrated. Crown 8vo. Price, cloth, \$2 net.

**ORTNER.**—*Treatment of Internal Diseases.* By Dr. NORBERT ORTNER. 8vo. 600 pages. By subscription only. Price, cloth, \$5 net.

**PFAUNDLER AND SCHLOSSMAN.**—*The Diseases of Children.* Edited by Professor M. PFAUNDLER and Professor A. SCHLOSSMAN. English Translation Edited by HENRY L. K. SHAW, M. D., of Albany, N. Y.; L. LA FETRA, M. D., New York. With an Introduction by L. EMMETT HOLT, M. D. Illustrated. 8vo. Four Volumes. By subscription only. Price, cloth, net, \$5 a volume.

**PIERSOL.**—*Human Anatomy.* Edited by GEORGE A. PIERSOL, M. D. Illustrated. Imperial 8vo. Price, cloth, \$7.50 net; half leather, \$9 net. In two volumes, by subscription only, half leather, \$10 net.

**RAMSEY.**—*Practical Life Insurance Examinations.* By MURRAY E. RAMSEY, M. D. A Handbook for Life Insurance Examiners. 12mo. Price, cloth, \$1.25 net.

**REMINGTON.**—*The Practice of Pharmacy.* By JOSEPH P. REMINGTON, Ph. M. New Fifth Edition. Illustrated. Price, cloth, \$6; sheep, \$6.50; half Russia, \$7.50.

**SCHMIDT.**—*Pain.* By Dr. RUDOLF SCHMIDT. An Accurate and Thorough Analysis of the Various Painful Sensations That Occur in Internal Diseases, Their Mode of Causation, and Correct Interpretation. Illustrated. Crown 8vo. Price, cloth, \$3 net.

**THOMPSON.**—*Glimpses of Medical Europe.* By R. L. THOMPSON, M. D. An Account of a Summer's Visit to the Prominent Medical Schools of Europe. With Many Illustrations Reproduced from Pen and Ink Drawings and Photographs. Illustrated. 12mo. Price, cloth, \$2 net.

**THOMSON AND MILES.**—*Manual of Surgery.* By ALEXIS THOMSON, F. R. C. S. (Ed.), and ALEXANDER MILES, F. R. C. S. (Ed.). Second Edition, Revised and Enlarged. Two Volumes. 515 Illustrations. Crown 8vo. Price, \$5 net.

## LONGMANS, GREEN & COMPANY, New York.

**BOSE.**—*Comparative Electrophysiology.* By JAGADIS CHUNDER BOSE, M. A., D. Sc., Professor, Presidency College, Calcutta. 8vo. Pp. xvii+760. Price, \$5.75.

**NEWMAN.**—*Movable Kidney and Other Displacements and Malformations.* By DAVID NEWMAN, M. D., F. F. F. S. G., Surgeon to the Glasgow Royal Infirmary; ex-President of Glasgow Medico-Chirurgical Society. With 25 Illustrations. 8vo. Pp. xii+237. Price, \$1.75 net.

**RIVERS.**—*The Influence of Alcohol and Other Drugs on Fatigue.* By W. H. R. RIVERS, M. D., F. R. C. P. 8vo. (Nearly ready.)

RUSSELL.—*The Reduction of Cancer.* By the Hon. ROLLO RUSSELL. Crown 8vo. 62 pages. Price, \$0.50.

This book consists of an examination of the view strongly held by distinguished medical men that cancer is to a great extent a disease due to overfeeding, to toxic beverages, and to worry. The results of a comparison, by the author, of different countries, communities, and occupations are found to support this view very fully.

*The Proceedings of the Royal Society of Medicine.* Vol. I. No. 3. Large square 8vo. Price, \$2.00. The *Proceedings* will be published monthly from November to July inclusive. The price of each monthly number will be \$2.00 postpaid. Annual subscriptions, \$16.

### THE MACMILLAN COMPANY, New York.

BARRUS.—*Nursing the Insane.* By CLARA BARRUS, M. D. Woman Assistant Physician in the Middletown State Homoeopathic Hospital, Middletown, N. Y.

CLARK.—*Neurological and Mental Diagnosis. A Manual of Methods.* By L. PIERCE CLARK, M. D., Senior Visiting Physician to the Hospital for Nervous Diseases, New York; Visiting Neurologist to the Randall's Island Hospitals and Schools; Consulting Neurologist to the Manhattan State Hospital, New York; Consulting Neurologist at the Craig Colony for Epileptics, Sonyea, N. Y., Assistant Neurologist at the Vanderbilt Clinic (Columbia University). And A. ROSS DIEFFENDORF, M. D., Lecturer in Psychiatry in Yale University; Member of the American Neurological Association, of the New York Neurological Association, of the New York Psychiatric Society, and of the American Medicopsychological Association, etc.

*Confessio Medici.* By the Writer of "The Young People." 12mo. Price, \$1.25 net.

A collection of delightful essays by a physician who has evidently read very extensively, and has gathered from a wide experience a fund of information which he draws upon with kindly humor and a literary grace that make his writing extremely attractive. The book is just the one which a weary doctor would enjoy reading before his fire after the day's work is done.

DAWBARN AND DELPHEY.—*An Aid to Materia Medica.* By ROBERT H. M. DAWBARN, M. D., Professor of Surgery and of Surgical Anatomy, New York Polyclinic Medical School; Professor of Surgery, Fordham Medical College, New York; Visiting Surgeon to the City Hospital, New York. Fourth Edition. Revised and Enlarged by EDEN V. DELPHEY, M. D.

KEITH.—*Cancer. Relief of Pain and Possible Cure.* By SKENE KEITH, M. B., F. R. C. S. (Ed.). Author of *Introduction to the Treatment of Disease by Galvanism, Electricity in the Treatment of Uterine Tumors, Gynecological Operations.* And GEORGE E. KEITH, M. B., C. M., Author of *Textbook of Abdominal Surgery*, with Mr. Skene Keith.

STORRING AND LOWEY.—*Mental Pathology in Its Relation to Normal Psychology. A Course of Lectures delivered in the University of Leipzig.* By GUSTAV STORRING, Dr. Phil. et Med. Translated by THOMAS LOWEY, M. A. Bibliography and Index. 8vo. Pp. x+298. Price, cloth, \$2.75 net.

The author of these lectures, who is now professor of philosophy in the University of Zurich, believes that the study of psychology heretofore has been too metaphysical. He regards conscious processes as deeply influenced by bodily conditions, and holds that a study of abnormal mental conditions, connected with known physical causes, will throw most light on normal mental processes. The book, in its fullness of discussion and illustration, becomes

a storehouse of facts in psychiatry, as well as important to the psychologist.

### THE MIDLAND PUBLISHING COMPANY, Columbus, Ohio.

RUTTER.—*Manual of Insanity. With Especial Reference to Criminal Responsibility.* By H. C. RUTTER, M. D., Medical Director, Mental and Nervous Department, Ohio Sanatorium, Columbus, Ohio. Formerly connected with the Hospital for the Insane at Dayton, Ohio; the Hospital for the Insane, Athens, Ohio; State Hospital for the Insane, Columbus, Ohio; Ohio Hospital for Epileptics, Gallipolis, Ohio. 295 pages. Price, cloth, \$2.50.

### OXFORD UNIVERSITY PRESS. London and New York.

*The Oxford Medical Manuals.* Edited by J. KEUGH MURPHY, M. A., M. D., M. C. (Cantab.), F. R. C. S., and G. A. SUTHERLAND, M. D., F. R. C. P.

ABEL.—*A Laboratory Handbook of Bacteriology.* By DR. RUDOLF ABEL, Medical Privy Councillor, Berlin. Translated by DR. M. H. GORDON, M. A., M. D. (Oxon.), B. Sc. 224 pages. Tenth Edition. Price, \$1.50.

ADAMSON.—*Skin Affections in Childhood.* By H. G. ADAMSON, M. D., M. R. C. P., Physician for Diseases of the Skin, Paddington Green Children's Hospital, and the North Eastern Hospital for Children. 284 pages. Illustrated. Price, \$1.50.

"Sound in information and practical in teaching."  
—*Hospital.*

"Cannot fail to be popular as it deserves to be."  
—*Practitioner.*

BARDSWELL AND CHAPMAN.—*Diets in Tuberculosis. Principles and Economics.* By NOEL D. BARDSWELL, M. D., Medical Superintendent, King Edward VII's Sanatorium, Midhurst, and J. E. CHAPMAN, M. R. C. S.

A full account of the practical value and cost of diets in general, and in every detail of the various diets which may with advantage be used in the treatment of tuberculosis.

BARWELL.—*Diseases of the Larynx.* By HAROLD BARWELL, M. B. (Lond.); F. R. C. S. (Eng.); Surgeon for Diseases of the Throat, St. George's Hospital; Laryngologist, Mount Vernon Hospital for Diseases of the Chest; Consulting Surgeon for Throat and Ear Diseases, Cripples' Home for Girls. 266 pages. Illustrated. Price, \$1.50.

"In the attempt to adapt it to the requirements of the general physician and student rather than to those of the specialist, the author has been successful."—*St. George's Hospital Gazette.*

BOLDE.—*Trachoma.* By DR. J. BOLDE. Translated by J. HERBERT PARSONS, D. Sc., F. R. C. S., and THOMAS SNOWBALL, M. B., C. M., Burnley. With an Introductory Chapter by E. TREACHER COLLINS, F. R. C. S. 232 pages. Royal 8vo. Price, \$3.

"This interesting monograph is a library in itself which (to use a hackneyed phrase) no ophthalmologist can afford to be without."—*Homoeopathic Eye, Ear, and Throat Journal.*

BOYLE.—*Practical Anesthetics.* By H. EDMUND G. BOYLE, M. R. C. S., Anesthetist to St. Bartholomew's Hospital, etc.

"As a rule, it is better for a student to avoid the larger books on anesthetics until he has studied the subject practically, but this book is preeminently one that he should buy and read carefully."—*St. Bartholomew's Hospital Journal.*

BROOKBANK.—*Life Insurance and Cancer.* By F. M. BROOKBANK, M. D., F. R. C. P., Assistant Physician, Manchester Royal Infirmary. 8vo. Pp. x+250. An account of life insurance from the practitioner's

er's point of view, whether employed as an examiner or consulted by a patient as to the prospects of acceptance or not. The question of increased risks for various causes is fully dealt with. The whole will be found to be practical and complete.

CORNER.—*Diseases of the Male Generative Organs.* By EDRED M. CORNER, M. C. (Cantab.), F. R. C. S., Assistant Surgeon, St. Thomas's Hospital, and Senior Assistant Surgeon, Great Ormond Street Hospital, etc. 279 pages. Illustrated. Price, \$1.50.

"A very readable little book, sufficiently full to be of use to the practitioner, and yet unburdened with anything that is not of practical value."—*Dublin Journal of Medical Science.*

CORNER AND PINCHES.—*Operations of General Practice.* By EDRED M. CORNER, M. C. (Cantab.), F. R. C. S., Assistant Surgeon to St. Thomas's Hospital; and Senior Assistant Surgeon, Hospital for Sick Children, Great Ormond Street, etc.; and HENRY IRVING PINCHES, M. A., M. B. 296 pages. Over 175 Illustrations. Price, \$5.50 net; postage 12 cents extra.

"The details of the many lesser operations in surgery, medicine, gynecology, ophthalmology, otology, etc., which a medical man may elect to perform, have been collected in this work. As the large textbooks take no notice of such details, their aggregation into one book should be a necessity for every busy general practitioner. Many illustrations have been prepared to illustrate the various points in their performance. It is large without being too big. It is clearly written, and gives just that amount of assistance which is likely to be needed."—*The Lancet.*

GEE.—*Auscultation and Percussion, with the other methods of Physical Examination of the Chest.* By SAMUEL JONES GEE, M. D., F. R. C. P., Honorary Physician to H. R. H. the Prince of Wales, Consulting Physician to St. Bartholomew's Hospital, etc. Fifth Edition. 325 pages. Price, \$1.50.

GUTH.—*Medical Lectures and Clinical Aphorisms.* By SAMUEL GEE, M. D., F. R. C. P., Honorary Physician to H. R. H. the Prince of Wales, Consulting Physician to St. Bartholomew's Hospital, etc. Price, \$1.50.

"We cordially recommend this book to be read, marked, learned, and inwardly digested" by all practitioners and students. It is small and easily carried, and the money it costs should be many times repaid by the valuable hints which it contains."—*Practitioner.*

GUTHRIE.—*Functional Nervous Disorders in Childhood.* By LEONARD GUTHRIE, M. D., F. R. C. P., Senior Physician to Paddington Green Children's Hospital; Physician to the Hospital for Paralysis and Epilepsy, Maida Vale, etc. Price, \$3 net; postage, 12 cents extra.

"We think Dr. Guthrie's work is likely to take its place as a standard work on the subject, and to be one of the most popular of the Oxford medical publications."—*The Practitioner.*

KEOGH.—*A Manual of Venereal Disease.* By Officers of the Royal Army Medical Corps. Introduction by The Lieutenant General of the Army, Sir ALFRED KEOGH, K. C. B.; History, Statistics, Invaliding, Effect in Campaigns, etc., by Lieut. Colonel C. H. MELVILLE, D. P. H., Secretary to the Advisory Board; Clinical Pathology, and Bacteriology, by Colonel LEISMANN, F. R. S., R. A. M. C.; Clinical Course and Treatment, by MAJOR C. E. POLLOCK, R. A. M. C. 282 pages. Illustrated. Price, \$1.50.

"The amount of information the book contains is great. The pathology, diagnosis, and treatment of syphilis are fully considered."—*St. Bartholomew's Hospital Journal.*

LOCKWOOD.—*Clinical Lectures and Addresses on Surgery.* By C. B. LOCKWOOD, Surgeon to St. Bartholomew's Hospital; late Hunterian Professor, Royal College of Surgeons, England; late Surgeon to the Great Northern Hospital. 307 pages. Illustrated. Price, \$1.50.

"Whatever Mr. Lockwood writes every thinking surgeon is compelled to read."—*British Medical Journal.*

"It is a work which every student should read before beginning his practice in the wards, and we feel that the same student will in the after years of his own professional work read the book again with an even deeper appreciation of its real helpfulness."—*The Medical Chronicle.*

McCANN.—*Cancer of the Womb: Its Symptoms, Diagnosis, Prognosis, and Treatment.* By FREDERICK J. McCANN, M. D. (Edin.), Fellow of the Royal College of Surgeons, England, Member of the Royal College of Physicians, London, Physician to the Samaritan Hospital for Women, London, Lecturer on Gynecology, Medical Graduates' College and Polyclinic, London. Fully illustrated. Price, \$7 net; postage, 12 cents extra.

"The book is one of great merit; it will be read with interest both by the specialist and practitioner as an authoritative exposition of the subject with which it deals."—*Edinburgh Medical Journal.*

POYNTON.—*Heart Disease, Including Thoracic Aneurysm.* By F. J. POYNTON, M. D., F. R. C. P., Assistant Physician to University College Hospital; late Sub-Dean to the Medical Faculty of University College; Physician to Out-Patients, the Hospital for Sick Children, Great Ormond street. 310 pages. Illustrated. Price, \$1.50.

A handbook dealing with the principles of physical examination, investigation, diagnosis, prognosis, and treatment of the more important diseases of the heart, including thoracic aneurysm. The aim of this book is to provide, within moderate compass, a guide to the study of heart disease, and clear indications for practical treatment.

SARGENT.—*Surgical Emergencies.* By PERCY SARGENT, M. B. (Contab.), F. R. C. S. (Eng.), Assistant Surgeon, St. Thomas's Hospital; National Hospital for Paralysis and Epilepsy, Queen's Square; and Senior Assistant Surgeon, Victoria Hospital for Children. Price, \$2 net.

"It is a book we can heartily recommend to the younger practitioner, who may at any moment be brought face to face with a serious emergency."—*Medical Journal.*

SUTHERLAND.—*Treatment of Disease in Children.* By G. A. SUTHERLAND, M. D., F. R. C. P., Physician Paddington Green Children's Hospital, and North Western Hospital, Late President of Section in Diseases of Children, British Medical Association. 310 pages. Price, \$1.50.

"We commend it to those who require a small and trustworthy work on the management of sick children."—*Lancet.*

TOD.—*Diseases of the Ear.* By HUNTER TOD, M. B., F. R. C. S., Aural Surgeon to the London Hospital, etc. Illustrated. Price, \$2 net.

"Will certainly take its place among the very best and most up to date works on the subject."—*Journal of Laryngology.*

TWEEDY AND WRENCH.—*Rotunda Practical Midwifery.* By ERNEST HASTINGS TWEEDY, M. D., F. R. C. P. I., Master of the Rotunda Hospital, Dublin; and E. M. WRENCH, Assistant Master. 464 pages. Fully illustrated. Price, \$6.

This is a practical book on midwifery, embodying the teachings of the Rotunda School. It contains no pathology or mechanics of obstetrics except where

either is essential for understanding the proposed treatment. The conduct of normal labor is dealt with, the closest attention given to every practical detail, however small, and all possible complications are treated in the same way. The authors devote the closest attention to the management of the puerperal state and the earliest disorders of the infant, also to the causes and immediate treatment of fever occurring in the puerperium. The work is illustrated by over one hundred drawings and original photographs.

**WAGGETT.—Diseases of the Nose and Throat.** By E. B. WAGGETT, M. D. (Cambridge), Surgeon for the Throat and Ear Department of the Charing Cross Hospital; Surgeon, London Throat Hospital, and Throat and Ear Department Great Northern Hospital and Central Hospital. Illustrated. Price, \$2 net.

"Short, concise, and, above all, readable. The illustrations are original and are very good."—*St. Bartholomew's Hospital Journal*.

**WALLACE.—Enlargement of the Prostate.** By CUTHBERT WALLACE, M. S., F. R. C. S., Assistant Surgeon to St. Thomas's Hospital, etc. 215 pages. Fully illustrated. Price, \$4.50.

This is a full account of this affection and its various consequences. The author first deals fully with our present knowledge of the anatomy, physiology, and pathology of the prostate, the work being copiously illustrated throughout by original drawings from specimens and photographs, also photomicrographs. He then treats of the anatomical characteristics of enlargement and its results, direct and indirect. The various means of treatment are then discussed, the more recent operative treatment is fully described, its results summarized, and the after treatment carefully dealt with. The work is a complete and exhaustive monograph, containing over one hundred and fifty illustrations in the text and a colored plate.

**WRENCH.—Rotunda Midwifery for Nurses and Midwives.** By G. T. WRENCH, M. D., Late Assistant Master of the Rotunda Hospital; with a Preface by the Master of the Rotunda. Illustrated. Price, \$2.

This is an entirely practical account of that part of midwifery which is essential for a nurse in the practice of her profession. The book is designed to embody the teaching of the Rotunda, and is fully illustrated, containing over one hundred illustrations, all of which are original.

### REBMAN COMPANY, New York.

**BARDELEBEN AND HAECKEL.—An Atlas of Applied (Anatomographical) Human Anatomy.** For Students and Practitioners. By Dr. KARL VON BARDELEBEN (Jena) and Professor Dr. THEODOR HAECKEL (Stuttgart). Under the collaboration of Dr. FRITZ FROHSE (Berlin), and with contributions by Professor Dr. THEODOR ZIEGLER. Only authorized English adaptation from the third German edition, by J. HOWELL EVANS, M. A., M. B., M. C. OXON, F. R. C. S. England. One chromo quarto volume containing 204 woodcuts, most of which are printed in many colors, and one lithographic plate, with corresponding pages of explanatory text. F. L. flexible leather, gilt edges. Price, \$10. Cloth, \$8. Sold by Subscription only.

**BELOUSOW.—Synoptical Description of the Nerves of the Human Body.** By A. K. BELOUSOW, Professor of Anatomy at the University of Charkov (Russia). Three large colored charts, mounted on linen, with colors accompanied by an explanatory text in Russian. By Dr. R. KERN, of Berlin. Explanatory text in

book form. Price, \$30. Full descriptive circular with 4 illustrations (one in colors) will be sent on application.

These three "synoptical charts of the nerves of man" illustrate the entire peripheral nervous system of the human body. The difficult problem of representing all the peripheral nerves with anatomical accuracy in a dummy has been solved by Belousow in the most masterly fashion. Chart I shows the nerves of the head, neck, thorax, and abdomen several times enlarged. Thus the upper part of the Chart (head and neck) is four times natural size. These dimensions have been chosen on account of the very great number of nerves displayed. The enlargement of the lower part of the Chart is less (twice natural size). Different colors have been used for various nerves in order to make the diagrams clearer. The colors have been chosen in such a way as not to offend or fatigue the eye. The size of the Chart (6 ft. 6 in. by 3 ft.) makes it possible to see all the details even at a considerable distance. Chart II (4 ft. by 2 ft.) shows the upper extremity, and Chart III (6 ft. by 2 ft. 4 in.) deals with the lower one. The three charts are mounted on linen, with rollers at top and bottom.

**BOCKENHEIMER AND FROHSE.—An Atlas of Typical Operations in Surgery.** For Practitioners and Students. By Dr. PH. BOCKENHEIMER and Dr. FRITZ FROHSE. Adapted (only authorized) English version by J. HOWELL EVANS, M. A., M. B., M. C. OXON, F. R. C. S. England. With 60 plates (12 in. by 9½ in.) in three color process prints, after water color drawings by Franz Frohse, with explanatory text and illustrations of the surgical instruments and appliances to which reference is made in the text. Handsomely bound in half leather. Price, \$16. Sold by subscription only.

**BRADDON.—The Cause and Prevention of Beriberi.** By W. LEONARD BRADDON, M. B., B. S., F. R. C. S., State Surgeon, Negri Sembilan, Federated Malay States. Royal, 8vo. Price, cloth, \$6.

**BULKLEY.—On the Relations of Diseases of the Skin to Internal Disorders.** With observations on Diet, Hygiene, and General Therapeutics. By L. DUNCAN BULKLEY, A. M., M. D., Physician to the New York Skin and Cancer Hospital, Consulting Physician to the New York Hospital, etc. Small 8vo. Price, \$1.50.

**BULKLEY.—The Influence of the Menstrual Function on Certain Diseases of the Skin.** By L. DUNCAN BULKLEY, A. M., M. D., Physician to the New York Skin and Cancer Hospital, Consulting Physician to the New York Hospital, etc. Small 8vo. Price, \$1.

**BULKLEY.—Local Treatment in Diseases of the Skin.** By L. DUNCAN BULKLEY, A. M., M. D., Physician to the New York Skin and Cancer Hospital, Consulting Physician to the New York Hospital, etc. Small 8vo. Price, cloth, \$1.

**CARRINGTON.—Vitality, Fasting, and Nutrition. A Physiological Study of the Curative Power of Fasting, together with a New Theory of the Relations of Food to Human Vitality.** By HERWARD CARRINGTON, Member of the Council of the American Institute for Scientific Research, Member of the Society for Psychical Research, London; Author of *The Physical Phenomena of Spiritualism*, etc., with an introduction by A. RABENOLD, M. A., M. D., F. R. C. S., Hon. Gynaecologist and late Senior Hon. Surgeon, Bradford Royal Infirmary. One 8vo. volume. Price, cloth, \$5.

**Conference on the Medical Philosophy of Medicine.** By an American Physician. A Manual for Students and Young Physicians. (Lans.) Price, \$1.50.

**Drugs and Their Action.** By a Lover of Science. (Lans.) Demy 8 vo. Price, cloth, \$2.50.

**FOLEY.—Hypnotism in Surgery and Physiotherapy. A Study of the Psychological, Psychophysiological, and Therapeutic Aspects of Hypnotism.** By Dr. (Med.) ALBERT FOLEY, Dr. Phil. (H. C.) at New York, U. S. Class. Superintendent, formerly Professor of Psychology.

- try and Director of the Provincial Lunatic Asylum, Zurich. Translated by H. W. ARMIT, M. R. C. S., L. R. C. P., from the fifth (German) edition. American edition, revised and corrected. One 8vo volume. Price, \$3.
- FORLÉ.—*La Sexual Question*. By Dr. (Med.) AUGUST FORLÉ, Dr. Phil. (H. C.) et Jur. (H. C.) Chigny, Switzerland; formerly Professor of Psychiatry and Director of the Provincial Lunatic Asylum, Zurich. Translated by C. F. MARSHALL, M. D., F. R. C. S. One 8vo volume. In the press. Price, \$5.
- FOURNIER.—*Treatment and Prophylaxis of Syphilis*. By ALFRED FOURNIER, Professor at the Faculty of Medicine, Member of the Academy of Medicine, Physician to the St. Louis Hospital, Paris. Only authorized English Translation of the Second Edition (Revised and Enlarged), by C. F. MARSHALL, M. D., F. R. C. S. Royal 8vo. Price, \$5. American edition, revised and corrected with an appendix by GEORGE M. MACKEE, M. D., Instructor in Dermatology at the New York University and Bellevue Hospital Medical College. Royal 8vo. Price, cloth, \$5.
- GOULEY.—*Surgery of Genitourinary Organs*. By J. W. S. GOULEY, M. D. Demy 8vo. Price, cloth, \$3.
- GUILLEMINOT.—*Electricity in Medicine*. By DR. W. H. GUILLEMINOT, Paris. A Textbook for Students and Medical Practitioners. Only authorized translation by W. DEANE BUTCHER, M. R. C. S. England, Surgeon to the London Skin Hospital. Synopsis of contents: Part I—Physics. Part II—Physiology. Part III—Medical Electricity. Demy 8vo. Illustrated. Price, \$4.
- JACOBI.—*A Portfolio of Dermochromes*. By Professor DR. E. JACOBI, of Freiburg. Only Edition authorized to be published in the English language. The text translated and adapted by J. J. PRINGLE, M. B., F. R. C. P., Physician to the Department of Diseases of Skin at the Middlesex Hospital, London. Price for the work, complete in three volumes, \$24 net, in full flexible leather with gilt edges. Sold only by subscription.
- This work contains plates of dermochromes beautifully reproduced in natural tints by a new four color process, illustrating the common diseases of the skin and venereal affections, which the general practitioner has frequent opportunities of observing in his daily practice. Each plate is accompanied by a page or more of explanatory text containing practical points in treatment.
- KLOPSTOCK AND KOWARSKY.—*A Manual of Clinical Chemistry, Microscopy, and Bacteriology*. By DR. M. KLOPSTOCK and DR. A. KOWARSKY. Only authorized translation by THEW WRIGHT, M. D., Buffalo, N. Y. Contents: Bacteriological Examination of: I. The Secretions and Deposits in the Mouth and Pharynx. II. Nasal Secretions. III. The Conjunctival Secretions. IV. The Sputum. V. The Gastric Contents. VI. The Faeces. VII. The Urine. VIII. The Urethral and Prostatic Secretions. IX. The Blood. X. Fluids Obtained by Puncture. XI. Diseases of the Skin. XII. The Usual Methods of Bacteriological Examination, Formulae of Stains, and Culture Media. (7½ in. by 5½ in.). 70 Illustrations, 30 of which are colored. Price, \$2.25.
- KRAFFT-EBING.—*Psychopathia Sexualis*. With special reference to Antipathic Sexual Instinct. A Medico-forensic Study by the late DR. R. VON KRAFFT-EBING, Professor of Psychiatry and Neurology, University of Vienna. Only authorized Translation from the Twelfth enlarged and revised German Edition by F. J. REBMAN. Royal 8vo. Price, cloth, \$4.
- LUKE.—*Inesthesia in Dental Surgery*. Second Edition. By THOMAS D. LUKE, M. B., F. R. C. S. E. Illustrated. Crown 8vo. Price, \$1.75.
- LUKE.—*Iconographia Dermatologica*. An Atlas of New and Rare Skin Diseases. Edited by Professor DR. ALBERT NEISSER (Breslau) and Professor DR. EDUARD JACOBI (Freiburg i. Br.), with the collaboration of a large number of prominent specialists throughout the world. Crown 4to. Published twice a year. Price, \$2.50 per issue.
- NEUSTAETTER.—*Skiascopy*. Phantoms and Diagrammatical Models, in Colors, with a Guide to the Theory and and Practice of Skiascopy. By OTTO NEUSTAETTER, M. D., Munich. Price, \$10.
- SABOURAUD.—*Regional Dermatology*. An Elementary Manual of Regional Topographical Dermatology. By R. SABOURAUD, Director of the City of Paris Dermatological Laboratory at the St. Louis Hospital. Only authorized translation by C. F. MARSHALL, late Assistant Surgeon to the Hospital for Diseases of the Skin, Blackfriars, London. Royal 8vo. 231 photo engravings in the text. Price, \$5.
- This is a new departure in dermatology. The book will strongly appeal to the practical mind of the busy practitioner.
- SCHLEIP.—*Hæmatological Atlas with a Description of the Technique of Blood Examination*. By Priv. Doz. DR. KARL SCHLEIP, Scientific Assistant in the Medical Clinic, University of Freiburg i/B. English adaptation of text by FREDERIC E. SONDERN, M. D., Professor of Clinical Pathology, New York Post Graduate Medical School and Hospital, Director Clinical Laboratory, New York Lying-In Hospital. With 71 colored illustrations, and many diagrams in the text. One quarto vol. ½ leather. Price, \$10.
- SCHRÖTTER.—*The Hygiene of the Lungs*. By Professor DR. L. VON SCHRÖTTER, Director of the Third Medical Clinic in the University of Vienna. Translated by H. W. ARMIT, M. R. C. S., L. R. C. P. Crown 8vo. Price, cloth, \$1.
- The work is intended to lay before the uninitiated reader (and also before the practitioner) the anatomical and physiological characteristics of the organs of respiration, and the best methods of protecting these organs. It deals with the more common ailments, and with the rational treatments, not only of the affected parts, but also of the causal agents, thus combining an elementary therapy with an elementary prophylaxis. In the most readable manner possible, this little book tells a useful story of the healthy and diseased lungs, a story which the practitioner who reads it will not despise, and which he will find of great value to give his patient to read.
- SENIATOR-KAMINER.—*Health and Disease in Relation to Marriage and the Married State*. A Manual Contributed to by many authors. Edited by Geh. Medizinalrat Professor DR. H. SENIATOR, and DR. (Med.) S. KAMINER. The only authorized translation from the German into the English language by J. DULBERG, M. D., of Manchester, England. In one handsome royal 8vo volume of 1237 pages. Price, cloth, complete, \$6.
- STRONG.—*Modern Electrotherapeutics*. An Elementary Textbook on the Scientific Use of Electricity and Radiant Energy. By FREDERICK FINCH STRONG, M. D., Instructor in Electrotherapeutics at Tufts College Medical School, Boston. Crown 8vo. Price, \$1.
- TIBBLES.—*Food and Hygiene*. An Elementary Treatise on Dietetics and Hygienic Treatment. By WILLIAM TIBBLES, LL. D., L. R. C. P., M. R. C. S., L. S. A., Medical Officer of Health, Fellow of the Royal Institute of Public Health, etc. Large crown 8vo. Price, cloth, \$3.
- WACHENHEIM.—*Chimatic Treatment of Children*. By FREDERICK L. WACHENHEIM, M. D., Chief of Clinic, Children's Department, Mount Sinai Hospital and Dispensary, New York. Demy 8vo. Price, cloth, \$2.50.

1. Orthopædic Heresies on Feet and Their Treatment,  
By L. R. G. CRANDON.
2. Rosenmüller's Fossæ and Their Importance in Relation  
to the Middle Ear, By FRANCIS P. EMERSON.
3. A Periosteal Flap for Use in Primary and Radical  
Mastoid Operations, with an Illustrative Case,  
By GEORGE A. LELAND.

**1. Orthopædic Heresies on Feet and Their Treatment.**—Crandon remarks that proper walking is the proper exercise for all the waking hours. Proper walking will restore the stiffened feet, and every minute of proper walking is a part of the treatment. Special exercises to restore the feet give the patient the wrong conception of his essential trouble. The foot symptoms are only a part of the general laxity, lack of freedom, and lack of balance. The author analyzes proper walking thus: 1. As the foot goes forward, the weight comes on the rounded heel. 2. As the sole comes to the ground the rounded heel throws the weight along the outer ridge of the plantar region to the distal end of the fifth metatarsal. 3. The toes take the ground in order, beginning with the little toe. 4. As the toes take the ground, the weight leaves the heel and the whole foot grasps the ground like a hand. Heel and great toe approach each other and every joint in the foot combines in "arching." Thus, the walking foot is not a "hock, arch, and hoof," but rather a hand with the heel a grasping talon. 5. All weight lastly rests on a triangle bounded by great and little toe, its apex behind at the ends of the middle metatarsals. From this triangle the final push is given as the foot leaves the ground.—The education of a patient may be outlined thus: Proper walking is made clear to the patient. He is told to get into the way of standing with the feet parallel, spreading his toes out enough to get the requisite broad base for balance, and to get Chinese slippers, strawsoled slippers, with soft top on the front, and none on the heel, in which he walks about at all convenient times. To keep this sandal on the foot the foot must at each step flex on itself in a prehensible fashion. He is encouraged, if it is feasible, to walk barefoot on turf or sand. He is not told to do toe and heel exercises, which tend only to stretch the atrophied plantar structures, but rather to practice standing on one foot, the other curled round his standing leg. The effort to balance in this position works every muscle of the foot and leg. He is told to stand, stockingfoot or barefoot, on a rubber doormat, legs crossed, feet as far apart as possible but parallel, with soles firmly planted on the mat. The leg which is behind is then swung round in front and crossed over to its former position, and so on, alternately crossing one leg in front of the other in a standing position. He is then told to walk in this cross legged fashion. These instructions are sufficiently specific to satisfy the patient. These exercises are interesting to the patient and will, therefore, be carried out. The patient thus educating himself cannot alternate between his mocassins, or wise shoeing, which is superior to mocassins, and his old shoes. Mocassins, or their

equivalent, are "foot-wear." Shoes, as they are made, are "hoof-wear."

**2. Rosenmüller's Fossæ and Their Importance in Relation to the Middle Ear.**—Emerson observes that pathological amounts of lymphoid tissue are present in Rosenmüller's fossæ in a large number of cases of chronic secretory and suppurative ears. This cannot be detected with certainty by posterior rhinoscopy alone, even where a good view of the vault is obtainable. In every chronic case there should be a routine digital examination. Where much tissue has been found and removed, the process of healing should be watched that no fibrous bands form. It is possible in a large majority of cases to predict the involved ear by the condition of the corresponding fossa. Results, where after treatment is followed, are particularly good in removing abnormal sensations, restoring uniform hearing without fluctuations in the partial or complete relief of tinnitus, and in the prevention of recurring salpingitis. If directions are given to blow one side of the nose at a time and carefully, the affected tube is no more apt to be infected later than its fellow.

of a Modification of the Ocular Test of Chantemesse,  
By WALTER W. HAMBURGER.

**1. A New and More Rational Method of Treatment of Leuchæmia by the X Ray.**—Stengel and Pancoast report their results with x ray treatment in leuchæmia. In any method of applying the treatment to the bone marrow the body should first be divided into definite regions, and each of these should be exposed with regularity. The manner in which they have mapped out the areas for exposure is as follows: (1) The feet, ankles, and lower halves of the legs. (2) From the middle of the legs to the middle of the thighs. (3) The right half of the abdomen and pelvis and the upper half of the right thigh. (4) The corresponding area on the left side, carefully avoiding the spleen in the earlier applications, but including its lower half later on. (5) The right half of the thorax and the right shoulder, including as much of the upper extremity as possible. (6) The corresponding area of the left side, again avoiding the spleen early, but including its upper half later on. (7) Later in the treatment the entire thorax and both shoulders are often included in one application, making the proper correction in time for the increase in distance. In stout subjects it may be advisable to treat this part of the body posteriorly as well. (8) When it is safe to expose the entire spleen it is advisable to approach it from the back and thus include the lumbar spine and the posterior aspect of the pelvis. Each of these regions is

treated in rotation and receives three successive exposures. In direct contrast to the older method of directly exposing the spleen from the start, their experience has demonstrated that this is an unwise procedure. This does not mean that the spleen should never be exposed, for to avoid it at all times would be almost impossible, and, besides, more or less exposure is no doubt necessary, but should not be attempted while the organ is still very large and the leucocytosis is still high. It is best to wait until the count is materially reduced and the patient's general condition has improved considerably. This mass of lymphatic tissue is far too susceptible to x ray influence, and the patient is not in a condition at first to stand the strain imposed by its exposure. Although this treatment requires a much longer period of time, the misleading tendency of a comparatively quick symptomatic cure, such as follows direct splenic exposures, is avoided. Applications confined mainly to the spleen reduce the size of that organ, destroy the leucocytes in the circulation, including the myelocytes, and possibly have some inhibitory influence, secondarily, on the cause, and hold the disease in check, leading to an impression that the case is cured, whereas statistics show that this is seldom the case. Applications to the bone marrow also reduce the size of the spleen and destroy the leucocytes circulating in the blood, but, in addition, they are more likely to reach and remove the cause of the disease. The spleen should be exposed at some time, but never until it is considerably reduced in size and the patient's general condition is markedly improved, and even then it should be done with caution. The proper time to stop treatment is still a somewhat uncertain question. The frequency of the applications should not be lessened until the general condition is normal and the size of the spleen and the leucocyte count nearly so. It would seem wiser to stop gradually rather than abruptly.

**5. Treatment of Chronic Trachoma.**—Prince states that the principal considerations are: First, select a germicide which is effective; second, prepare the infected surface in such a manner that the germicide may act; third, combat corneal complications (pannus and ulcers); fourth, correct the condition of the lids, which may cause relapsing inflammation (entropion, cysts, etc.). The remedies used are copper sulphate, mercuric oxide, tannic acid, silver nitrate, boric acid, jequirity. In the empirical use of drugs to combat chronic trachoma, perhaps no remedies have been so extensively used as copper sulphate and silver nitrate, the former in the absence and the latter in the presence of secretion. The removal of trachomatous material can be done by squeezing out of the follicles. After squeezing scarifying, and milking out all the trachomatous material, apply a 10 per cent. solution of copper sulphate in glycerin, and scrub with cotton, so as to force it into the tissues. Rinse with water to remove excess, and prevent corneal irritation. A Belgian method, which has been popular in the army, has been the rubbing on with the finger of powdered boric acid. Ulcers occurring in conjunction with trachoma show little tendency to heal until the trachomatous infection has been brought under control by the germicidal action of the blood, chemical remedies, or actual cautery. Following this, a healing tendency is usually rapidly established; pannus pro-

ceeds and nutrition follows. The favorite cautery in these cases is the Gruening platinum probe, which is heated in the Bunsen flame, and applied to the entire area. When the necrosis is shallow, rapid recovery usually follows, but when the layers of the cornea are destroyed down to the membrane of Descemet, it is usually found necessary to make a paracentesis through the floor of the ulcer, and keep the opening from closing by the repeated applications of a probe until the healing tendency has been established. The establishing of a fistula by cauterizing the margin of a perforating ulcer will often bring about a rapid change from a progressive destruction to rapid reparation. As an aid to repair iodoform has held first place, but argyrol in 25 per cent. solution every two hours is well tolerated, painless, and efficient. Hypopion, in conjunction with trachoma, is similarly treated. It is the aim to divide the floor of the ulcer and carry the incision into the sound tissue on both sides. The pus escapes with the aqueous humor, and the anterior chamber is emptied twice daily with a probe, when found necessary, until no more pus is formed, after which the opening in the cornea is allowed to heal. Of jequirity the author says that he commences treatment with a very weak infusion, one fourth of 1 per cent. This is employed twice a day for two days, during which time the tissues stretch to accommodate the infiltration. In case the eye is sensitive to the remedy, a solution of this strength is usually sufficient to produce the desired reaction. In case toleration exists the strength of the solution may be increased to one half of 1 per cent. The eye soon develops tolerance, and commences to improve before the discontinuance of the use of the remedy. It is desirable to secure a decided membrane covering the surface of the tarsal conjunctiva. It may extend over the retrotarsal fold, in which case care will be necessary to separate the surfaces which lie in contact or adhesion may take place. Of the bean, the author says that it will be found very difficult to remove the cortex of the bean and reduce it to a powder unless one is provided with the proper means. The suggestion is to get a hand pepper grinder, with which many persons grind pepper fresh while at table. The first turn breaks the cortex. The beans are emptied out, the cortex removed, and the kernels replaced in the grinder. They are ground through several times until a moderately fine powder results. Divide into one grain powders. One powder in two drachms of a 2 per cent. solution of boric acid will be the initiative dose. It is ready for use in fifteen minutes, and should be made fresh every day.

2. Therapeutics of Vasoconstriction and Vasodilatation. By GEORGE B. WATSON.
3. The Treatment of Endometritis by Irrigation and Drainage. By ALBERT ABRAMS.
4. Surgical Transplantation of the Reticular Layer of the Uterus. By ALBERT ABRAMS.
5. The Treatment of Endometritis by Irrigation and Drainage. By ALBERT ABRAMS.

3. The Treatment of Endometritis by Irrigation and Drainage. Crochet remarks that the (11)

damental principle in the treatment of endometritis, in whatever form encountered, is or should be drainage, not of the cavity alone, but drainage of the submucous glands as well. In conjunction with drainage, cleanliness is likewise essential. This should comprise removal of accumulated secretion and debris from the cavity of the uterus, and agglutinated, viscid secretion from the surface of the mucous membrane of the cervix by copious irrigation, repeated at least daily. This is accomplished by means of a special double current or return flow irrigator, made sufficiently small to permit introduction through the canal without previous forcible dilatation such as is required for curettage. Sufficient dilatation for introducing this small irrigator is secured, when necessary, by means of conical electrode dilators, introduced through the canal while connected with the negative pole of the galvanic current. A moderate current of 10 milliamperes will suffice and this does not irritate or cauterize. Thus negative electrolysis is utilized to free the canal for irrigation and subsequent drainage. As a rule this irrigator may be introduced without the preliminary dilatation, or it may be converted into an electrode by insulating it with a piece of rubber tubing slipped over it, there being an attachment for connecting it with the wire from the battery. In this manner its introduction is facilitated. Throughout the irrigation the current should be continued in force in the same moderate strength. The solution used for irrigation will vary with the individual condition under treatment. It may be simple sterile water, normal salt solution, potassium permanganate (1 to 3,000 or 5,000), hydrogen peroxide (1 to 4), lysol (a drachm to 2 qts.), which facilitates removal of the viscid secretion, or iodine in the strength of one drachm of the tincture to three or four pints of water. When iodine solution or other astringent or antiseptic solutions are used in the uterus care must be observed to let all of the solution escape before the irrigator is withdrawn or contraction of the cervix may occur, causing retention of the solution and provoking severe pain. This is the most effective method of cleansing the cavity and making application thereto.

**5. Intramural Transplantation of the Round Ligaments.**—Barrett describes his operation. He remarks that it occurred to him that by going through the median line to do work in the abdomen and pick up the ligaments, he could then carry them through the internal ring and fasten them at some point without tedious dissection, as was done by Edebohls' Alexander operation following celiotomy. After considering the many ways in which the ligament could be dealt with such as a puncture over the internal ring, tunneling over the aponeurosis, etc., the most feasible plan seemed to be to pass a curved ligature carrier under the aponeurosis to the internal ring and there enter the abdomen and secure the silk ligature which had been previously placed upon the round ligament two thirds of the distance from the uterus to the internal ring. The forceps are then withdrawn and along with them the silk loop, and with this the loop of round ligament, which is sewed to the under side of the aponeurosis over the rectus muscle, and then if long enough it is sewed to the loop on the opposite side. We now have the ligament running from the uterus

to the internal ring, then under the aponeurosis over the rectus muscle to or near the median line, where it is sewed, then back to the internal ring, then through its normal course to the labium. It is shortened by the distance of its excursion inward and back to the internal ring. In some cases the author has made a two and one half inch incision transversely down to the aponeurosis of the external oblique, then a median longitudinal incision to do the work in the abdomen, then the ligature carrier was pushed through the aponeurosis at the outer ends of this transverse incision, and was carried through the internal ring to pick up the control silk on the ground ligament. This, while it makes a splendid operation, is only advisable when the complications are slight. The median incision through all the layers is preferable for severe complications. In addition to the round ligament work it has seemed best at times to shorten the sacrouterine ligaments. We should remember that the work of ligaments is to carry the uterus; they are not intended to do the work of the pelvic floor, and this latter structure should be repaired if inefficient. This operation makes the most anatomically perfect operation which has yet been proposed which does not require tedious dissection to find the ligament, and has the distinctive feature of having the ligament leave the abdomen at the proper place—the internal ring. We cannot hope in our operative work to improve upon the normal condition; no operation can anchor the ligament farther out or a less distance and be quite as right. Alexander's operation fails because most cases of retrodisplacement are complicated. An operation to be widely useful must open the abdomen for inspection and correction of complications. It should be capable of being combined with the best incision for doing work, it must not create false ligaments which will not evolve during pregnancy and involute thereafter. There must be no abnormal arrangement of natural ligaments which allows them to run transperitoneally. When the round ligaments are employed the inner, stronger portion of the ligament should be chosen. An operation for retrodisplacement must often be performed after much other operating, and so should not offer any tedious technicality such as is found in the external search for the ligaments.

**2. Treatment of Dyspepsia.**—Hutchison states that alterations in the functions of the stomach which produce the symptoms termed "dyspepsia"

tend to be in the direction of either excess or defect. The physiological functions of the stomach are: Secretory; motor; sensory; and absorptive. Taking up these in order: 1. Secretory functions. An excess of secretion may be manifested by a total increase in the amount of gastric juice secreted (hypersecretion, gastrosuccorrhœa) or it may affect the hydrochloric acid alone (hyperchlorhydria). Conversely the total amount of gastric juice may be deficient (hypochylia), or it may even be absent altogether (achylia) or the hydrochloric acid may alone be deficient (hypochlorhydria). 2. Motor functions. The more passive function of "tonicity" must be distinguished from active "motility." Defect of these results in "hypotonicity" and "defective motility" respectively. Mere want of tone is responsible for many cases of "splashing stomach"; if the active movements are also defective, there is delay in the passage of the food, but no actual stagnation as in pyloric stenosis. Increase of the motor functions is less important than defect, in the production of dyspepsia, but "pyloric spasm" may be regarded as an increased manifestation of the active movements, usually induced by the presence of an ulcer or fissure. 3. Sensory functions. Exaggerated sensibility of the stomach (hyperæsthesia) is a common cause of gastric pain, and can be assumed to exist when the secretion is normal and there is no evidence of organic disease. Of defective sensibility or anæsthesia of the stomach, nothing is known. 4. Absorptive functions. The absorptive power of the stomach is at best limited and, as far as is known, alterations in it play no part in the production of functional dyspepsia. Of course any of these disorders may exist alone, but usually two or more coexist in the same cases. Treatment directed to the nervous system is, of course, applicable to all cases—*e. g.* rest, liberation from worry and mental work, change of air and scene, hydrotherapeutics, etc. Taking up the whole functional disorders as classified before: 1. Secretory disorders. (a) Excess. Dietetic treatment. Articles acting as stimulants of secretion must be avoided, such as salt, meat extracts, and meat soups, alcohol, spices, and condiments. Milk is a good food, in that it restrains secretion, but except in very bad cases, good results will be obtained with a diet of milk, eggs, meat, and fish—the starchy foods being strictly limited. Medicines. The bromides are useful in excessive gastric secretion, by lessening the activity of reflex processes. In general drugs should be used to neutralise the secretion after it has formed, rather than to check it. (b) Defective secretion. Diet. Here stimulating articles of diet should be given, such as meat extracts and soups, alcohol, etc. The food should be as well cooked and served as possible, so as to stimulate the flow of "psychic" gastric juice. Medicine. Drugs may be employed in these cases either to stimulate the natural secretion or to replace it artificially. The bitters are the chief stimulants of secretion, and should be given in solution and shortly before meals. Both hydrochloric acid and pepsin can be replaced artificially, but their use in actual practice has been disappointing. It is difficult to give enough hydrochloric acid to be of use, while as regards pepsin it is difficult to obtain an active preparation, and further it is inactive unless

the gastric contents be raised to their normal level of acidity. Ferment therapeutics are almost worthless. 2. Motor disorders. (a) Excess (Pyloric spasm). Diet. The diet here must be as bland as possible, consisting mostly of milk, supplemented by soft farinaceous foods. Medicine. The drugs to be used are those which lessen the acidity of the gastric juice, and which diminish the hyperæsthesia of the stomach. Hydrotherapeutics. The most useful measure is the local application of heat to the epigastrium by means of fomentations or poultices. (b) Motor defects (Atony). Diet. The most important rule is to avoid burdening the stomach with a mass of heavy contents which tends to distend it by its weight. Fluids are particularly harmful, and all tough, hard, and indigestible articles should be forbidden. The diet should be "dry." Medicine. No drug is known which can be relied upon to increase the tonicity and muscular efficiency of the stomach. Strychnine and alcohol possess this power in some degree, however. Physical treatment. Massage is sometimes of service, by increasing the external support of the stomach. Electric treatment is of very doubtful value. 3. Sensory disorders. Hyperæsthesia. Diet. This should be bland, but it may be necessary to feed the patient up in spite of the pain at first produced. Medicine. Bismuth is an efficient gastric sedative, bromides, hydrocyanic acid, hyoscymus, chloral, and even opium may also be used. Physical treatment. The local application of heat is the most potent of all methods of relieving oversensibility.

4. The Pancreatic Reaction in Urine.—Watson has studied Cammidge's so called pancreatic reaction in the urine of persons suffering from disease of the pancreas. His results go to confirm the view that there is a definite and important relationship between the pancreatic reaction in the urine and disease of the pancreas. He divides the cases in which the pancreatic reaction is present into the following groups:—1. Those in which there is definite clinical or pathological evidence of serious organic disease of the pancreas—for example, acute and chronic pancreatitis, usually associated with disease of the bile ducts. 2. Those in which the reaction is associated with pronounced arteriosclerosis, a condition usually accompanied by more or less sclerosis in different glands. 3. Those in which the reaction is dependent upon congestion and catarrhal conditions of the gland ducts and substance, with associated toxæmia—*e. g.*, advanced heart disease, appendicitis, pneumonia, malaria, and the like.

3. **Cancer of the Prostate.**—Walker states that sixteen per cent. of cases of enlarged prostate undergoing operation are due to malignant disease. Of forty cases studied by him, the average age was sixty-five years. But malignant disease of the prostate is, however, of slow growth and the symptoms which it produces are due to urethral obstruction and nerve pressure, so that the disease has spread widely before they appear. It is probable that the growth actually commences at a much earlier age, so that age is of no great value in making a diagnosis except that an enlargement of the prostate which commences much under fifty is more likely to be malignant than simple. Difficult micturition is the cardinal symptom, being most frequent, most prominent, and usually the earliest. Next to difficult micturition an increase in the frequency of the act is the symptom oftenest complained of. It is not often due to cystitis or to a septic condition of the urine, but the growth spreads outside the bladder along the anterior and posterior walls and so fixes the urethra that it acts as an immobile tube which drains off the urine. Pain is of course often present, and is of three types. (a) Pain connected with micturition is usually along the urethra and in the penis, is experienced either at the commencement or after micturition, and is aching and not severe. (b) Pain apart from micturition but due to urinary obstruction. This is aching in character and felt over both kidneys. (c) Pain independent of micturition or obstruction. This is felt in the penis, the rectum, or the lower part of the back. The pain in these cases is never agonizing; its characteristics are that it is constantly present, that it persists for months or years, that there is no connection with micturition or movement, and that drug treatment gives no relief. Hæmaturia is usually absent, being noted in only twelve per cent. of the cases. This is due to the fact that the growth is of the hard scirrhous type, comparatively avascular, and not prone to ulcerate. Emaciation is not so marked as in other forms of malignant disease. Intestinal obstruction may complicate matters, being due to extensive infiltration of the rectal wall. The inguinal lymph glands are frequently the seat of secondary growths, and are enlarged, hard, and discrete. On examination the prostate is found to be hard, irregular, and fixed. Many cases, when first seen, are too far advanced for radical operation; catheter life may become necessary, and opium be required to relieve the pain. The methods of operation open to choice are the suprapubic and perineal, the writer preferring the latter. Digital enucleation from the bladder is often very difficult to perform. Perineal operations may be either prostatectomy as usually performed for the removal of benign enlargements of the prostate, or more complete removal of the prostate, prostatic urethra, sheath of pelvic fascia, portion of the bladder base overlying the prostate, and seminal vesicles.

4. **Intraspinal Analgesia.**—McGavin, from a study of fifty cases of intraspinal analgesia, is convinced that it is a method of the greatest value, and in careful hands, perfectly safe. The opinion of patients as to its merits is universally favorable, and the after effects of the drug are really trivial in the majority of cases, while in the remainder they bear comparison very favorably with those of the various general anesthetics. The analgesia provided is, as a rule, of the most perfect order, available to all operations within the area involved. The excessive rapidity of the pulse noticed in some of the cases subsequent to injection has probably nothing to do with the drug itself; it is amply accounted for by the excitement of the patient, and it rapidly subsides on the discovery that the operation is really painless. The frequent occurrence of tympanitis is clearly explicable on the supposition that the rami communicantes of the sympathetic system of nerves are equally affected by the injection, the bowels becoming for the time being partially paralyzed. The effect of the drug is not exerted upon the spinal cord itself, but upon the posterior, and to some extent upon the anterior nerve roots.

5. **Renal Hæmorrhage in Nephritis.**—McNab's article is based on a series of thirty-one cases of renal hæmorrhage occurring in chronic interstitial nephritis. These thirty-one cases were selected from 2,229 cases of granular kidney, a frequency of one in seventy-two, probably far too low. It was at first thought that hæmorrhage was always a late complication, but of the cases here reported the average age was 26.2 years, the youngest being eight years and the oldest sixty-four years. In twenty-one cases there were no signs of disease other than the state of the urine, hæmaturia being the first indication of a chronic nephritis and calling attention to it at an early stage of the disease. In only six of the thirty-one cases were any changes found in the fundi of the eyes. Sex had little or no influence in the causation of hæmaturia, twenty-nine cases being in men, and sixteen in women—the usual proportion in granular kidney. Renal hæmorrhage is usually recognized by the fact that the blood is intimately mixed with the urine. In doubtful cases cystoscopic examination is most useful. The differences between subacute nephritis and renal hæmorrhage in chronic nephritis are that in the latter there is little or no oedema, the amount of blood and albumin fluctuates from day to day, and the course of the case is different. The hæmorrhage may persist for weeks and months, and when it does the urine is of low specific gravity and contains casts with a trace of albumin. Hæmaturia due to renal tuberculosis may be recognized by the more marked nocturnal frequency, by the results of cystoscopic examination, and by tubercle bacilli being found in the urine. Renal calculi give a typical history and may be detected by the x rays. In malignant disease of the kidney in the later stages there is usually a unilateral tumor. The hæmaturia of granular kidney does not seem to depend on purely mechanical causes such as high arterial tension and deterioration of the vessel walls, but is more probably due to local infiltration set up by some toxin. The prognosis depends almost entirely on the degree of kidney change that is present.

Rest in bed, purgatives, and a diet consisting chiefly of milk, bread, and butter will, as a rule, be sufficient to stop the bleeding. Hæmostatics, such as calcium lactate or calcium chloride, may be tried, but are hardly necessary. Iron in some form is useful during convalescence. Recurrence is extremely probable, for the cause, the chronic nephritis, still remains. Surgical treatment may be necessary in rare cases of severe hæmaturia occurring early in the disease.

1. Aspiration by Water Power. Its Applications in Operative Surgery, By F. LÉGUEUR.
2. Simple and Complicated Obesity, By MARCEL LABBE.
3. Brudzinski's Sign, By R. ROMME.

#### 2. Simple and Complicated Obesity.—Labbe

says that there have always been distinguished two types of obesity; in the one the people are florid, vigorous, and looking well, in the other cachectic, feeble, and pale. Physicians have been accustomed to designate the former as sanguine and plethoric, the second as anæmic and lymphatic, while popular language has distinguished them as good fat and bad fat. These two types are the results of different pathological processes. The one is simple florid obesity, in which the augmentation of weight is due to the accumulation of fat in the organism; the other is complicated, and in it the augmentation of weight is due in part to accumulation of fat, in part to the retention of water. Complicated obesity is a sequel to the simple form. The fatty infiltration causes the heart excessive fatigue and diminishes the resistance of the myocardium, the intoxication produced by supraabundant alimentation, especially by supraalimentation with meat, gradually produces changes in the kidney and brings about renal sclerosis. The alterations of the heart and kidneys, the fatal but slow result of habitual supraalimentation, may form a complication if an intercurrent disease causes a strain on the kidney or the heart. Pulmonary emphysema, which is frequently observed in these patients, is one of the causes that favor insufficiency of the myocardium. Hence in certain patients a florid obesity rapidly gives way to a complicated, cachectic obesity, with its train of visceral alterations and functional insufficiencies. The combination of Bright's disease with myocardic insufficiency results in a retention of the chlorides with the œdema.

April 1, 1908.

1. The True Conception of the Antibody. Its Relation to Immunity, By FOIX and MALLEIN.
2. Acute Enteritis and Appendicitis. Late Perforation of the Intestinal Ulcerations, By A. BROCA.

#### 1. The True Conception of the Antibody.—

Foix and Mallein say that every antigenous substance introduced into the organism provokes the appearance of another substance which is called antibody. The number of substances to which these terms might be applied is great, but the application of the terms is restricted to the antigenous microbes and their toxins and the antagonistic substances called forth by them. The antitoxines are antagonistic to the toxins, the antibodies to the microbes themselves. If one injects into an animal of the species A blood from another animal of the species B there are formed in the organism of the animal A

precipitating substances in opposition to the serum B, agglutinants and hæmolytants in opposition to the blood corpuscles. The same formula can apply to every microbic infection, whether spontaneous or experimental. We have then precipitants, or precipitins, agglutinants, or agglutinins, cytolisants, or bacteriolysins. There is in addition a set of antibodies that favor the phagocytic action of the white blood corpuscles. These are the stimulins of Metchnikoff and the opsonins of Wright and Douglas. The author deals at some length with each of these substances, and then enters into the question of the nature and origin of the antibody and briefly presents the theories of immunity.

2. **Acute Enteritis and Appendicitis.**—Broca describes a case in which this puzzling complication was present in a boy thirteen and a half years old.

April 1, 1908.

Diagnosis of Pancreatic Insufficiency.

By PROFESSOR R. LEPINE.

**Diagnosis of Pancreatic Insufficiency.**—Lepine reviews the literature on this subject and finally gives as the best signs of faulty external secretion of the pancreas abundance of fat and rarity of soap in the fæces, with diminution of the sulphur products in the urine. The mydriasis provoked by adrenalin is an index of a deficit of the internal secretion. It is readily to be seen how much the diagnosis of a functional insufficiency of the pancreas is to be desired.

#### MUENCHENER MEDIZINISCHE WOCHENSCHRIFT

March 31, 1908.

1. The Crime of Drunkenness and Its Legal Penalty, By HEILBRONNER.
2. Therapeutic Contributions to the Arc Light Treatment of Skin Diseases, By RIEDEL.
3. Concerning a Rare Complication after Operations on the Stomach, By STIEDA.
4. Concerning Thymus Persists and Apoptiform Thymus Death, Together with Remarks Concerning the Relations between Persistence of the Thymus and Exophthalmic Goitre, By HART.
5. The History and Technique of Orthodiagraphy, By MORITZ.
6. The Treatment of Spasm of the Cardiac Orifice, By GEISSLER.
7. Concerning Tendinitis Ossificans Traumatica, By HÖRING.
8. A Case of Dementia Posttraumatica with Unusual Accompanying Symptoms, By TRESPE.
9. The Treatment of Sore Throat, By BERLINER.
10. The Sterilization of Rubber Gloves, By FLATAU.
11. A Typical Case of Sudden Interruption of the Menses with Sore Throat, By SEHLBACH.
12. The Production of Instantaneous X Ray Pictures, By KASTLE, RIEDEL, and ROSENTHAL.

2. **Arc Light Treatment of Skin Diseases.**—Riedel reports twenty-five cases of skin disease, including various forms of eczema, acne, sykosis, pruritus ani, scrophuloderma, tuberculosis, and syphilis, successfully treated with arc light.

3. **Rare Complication After Operations on the Stomach.**—Stieda reports the case of a woman fifty-five years of age on whom resection of the pylorus was performed. The operation was followed by persistent vomiting of a slightly bloody fluid. Introduction of the stomach tube showed that the stomach was empty. As the vomiting increased and threatened the life of the patient another laparotomy was performed, when the tumour was

opened, the stomach found perfectly empty, and no explanation of the vomiting was discovered. She died two days later, and on autopsy the only objective conditions to be found were a stippling of the gastric mucous membrane, a small ulcer near the insertion of the sutures at the place of anastomosis, and a hematoma at the occlusion suture of the stomach. There was no peritonitis, or other condition to explain the vomiting. Hence the latter was referred to an extraordinarily increased reflex excitability in the region. He mentions also two other patients who died of hiccough after operation, due apparently to a nervous condition, as no cause was revealed at the autopsies.

**5. Orthodiagraphy.**—Moritz describes the apparatus employed in orthodiagraphy, with the manner of its employment, and mentions as advantages possessed by this method its quickness and simplicity, the cheapness of the measurements taken as compared with photographs, the possibility of simultaneous observation of the processes in the thorax of the patient while the measurement is being taken, and the determination whether the patient breathes quietly and in what phase of respiration the measurement is taken. It is also possible to produce on one and the same paper various cardiac measurements in different respiratory phases.

**6. Treatment of Spasm of the Cardiac Orifice of the Stomach.**—Geissler has devised a sound with an india rubber bulb attachment to be passed through the œsophagus until the empty bulb is in the spasmodic stricture, which is then to be dilated by inflation of the bulb.

**7. Tendinitis Ossificans Traumatica.**—Höring describes a case of ossifying tendinitis met with in a man fifty-six years of age, of good health, who had received a severe blow on the left tendo Achillis.

**9. Treatment of Sore Throat.**—Berliner recommends the use of a protogol ointment introduced through the nose.

## Proceedings of Societies.

### MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

*Special Meeting, Held on February 3, 1908, at the Staten Island Academy, St. George, Borough of Richmond.*

Dr HENRY C. JOHNSTON in the Chair.

**Radium.**—Dr. ROBERT ABBE made an address on radium and its use in the treatment of disease. He said that for the past five years he had been experimenting practically with this agent, and that he was now beginning to see daylight. When radium was first exploited in the medical world, it was announced that it was a wonderful cure for cancer, and, as was commonly the case with such premature allegations, disappointment resulted. There was, naturally, a great deal of "faking" in connection with the subject, and charlatans everywhere vaunted their ability to perform miracles with radium. To Dr. Abbe it appeared that the real value of the agent, if such it had, could be demonstrated only by persons who were thoroughly conversant with regular surgical procedures in the treatment of cancerous and other growths, and he undertook to make an extended scientific test of the matter. He recog-

nized that no dependence could be placed on photographs of the pathological conditions to be represented, and he therefore tried a new method of securing a record of cases before, during, and after treatment. This was by the making of casts from life, which, when accurately colored, showed exactly the existing conditions. No treatment other than the radium applications was given.

The speaker then gave a résumé of the history of the discovery of radium, and some account of its effects on cell and animal life. There appeared to be no limit to its penetrating power, as was shown by tests with the most opaque substances, such as lead and other metals. When mice were subjected to its influence they became affected with spinal meningitis and were paralyzed in their hind legs. On their skin, as well as on human skin, burns were produced similar to those from the x ray. Its value in cancerous and other neoplasms seemed to be due to its destructive agency on new growing cell life.

Dr. Abbe then presented, with brief descriptions of the cases and their treatment, a very large series of the beautiful and accurate casts which he had made. For ordinary warts (papillomata), such as were commonly met with on the hand, one application of radium for fifteen minutes, he said, would suffice for a perfect cure in almost all instances. The radium was efficient in all stages of the change of tissue between normal hypertrophic growth and malignant disease. Many cases of so called cancer of the tongue, he believed, were simply papillomata of the same kind seen on the cutaneous surface. There were, of course, true cancers of the tongue, however, and it was probable that these papillomata were oftentimes the precursors of cancer. Leucoplakia of the mouth was readily cured by means of radium, and it seemed now to have been demonstrated that cancerous growths were not malignant at first. Epithelioma might go on for years without the occurrence of metastasis. The casts were shown of a very severe case of this kind, which had been perfectly cured by seven applications of radium for an hour at a time. Three years had now elapsed, and there had been no return whatever of the disease. A cancer of the nose had been cured by two applications, and the same was true of one affecting the eyelid and corner of the eye. Tuberculous lesions of the hand and the heel, in the same patient, which had existed for some years and resisted all other forms of treatment, had been cured by seven applications of radium of an hour each. An eroding epithelioma of the cheek had been perfectly cured by three similar applications, and a cancer behind the ear and extending down the neck, by four applications. One of the most interesting of the cases was an extensive and most disfiguring sarcoma of the eyelid, which had been cured by four applications. Here the deformity and loss of tissue appeared to have been beautifully repaired by a reassembling of the normal cells through the agency of the radium—in fact, forming the lid over again. In a mixed sarcoma of the parotid region and a giant celled sarcoma of the jaw, involving the bone, the result had been equally satisfactory. In the latter instance fifteen applications were required to effect the cure. The more malignant and "juicy" a growth was, the more readily and quickly it seemed to yield to the effect of radium. The casts of all these cases and many

others, showing the condition before, during, and after treatment, were presented by Dr. Abbe.

He said that he did not care to speak of the use of radium in internal cancer. He had not ventured into this field to any great extent, and unfortunately most of the cases which had been sent to him had been too far advanced to be benefited by any treatment. He did not believe, however, that these internal growths differed materially from the superficial ones. Like the latter, they appeared to consist of cells growing wild, as it were. It seemed to him that the results which he had obtained with radium went to demonstrate that cancer could not be of bacterial origin.

The great objections to radium were its exceeding rarity and high cost. The purest to be had was the German radium bromide, which was the standard of activity, and the commercial value of this was \$1,000 a cell of 10 milligrammes. The supply of this was extremely limited, for, while radium was found in some other localities, the expense of mining was far too great to render the supply available. The only place from which it could be obtained was the one mine in Bohemia where it existed in the pitchblend from which the uranium was extracted for the manufacture of the Bohemian glassware. On account of the possibility that the supply of pitchblend might become exhausted, and the large population engaged in making glass might thus be deprived of their livelihood, the government now strictly limited the amount of mineral to be mined each year to a certain fixed quantity. Hence the pure radium bromide which came from this mine could scarcely be obtained at all at present. Before these regulations were quite so strict Dr. Abbe had fortunately been able to secure several specimens of radium, and he had one tube containing six cells (or 60 milligrammes) of the pure bromide, which was valued at \$6,000. The risk of handling radium was also very great. On two occasions in his experience (one of them very recent) the little container had fallen, and as it exploded the radium had been scattered about in all directions. By the extraordinary power of the radium, however, he had succeeded in obtaining photographs showing every particle of it; so that he was able to recover it all from the floor. It was of value to know that the less pure specimens of radium were still of service in the treatment of disease. The only reliable test of the activity of such specimens was the photographic one. By testing them through a lead disc, in comparison with the photographic power of the standard radium bromide, the exact degree of their activity could be determined. It had been shown that a weak specimen could be used with good effect if its application was maintained for a sufficient length of time. Thus, one which the photographic test had demonstrated to be ten times less energetic than the standard must be applied for ten times as long as the latter at each sitting.

During the evening Dr. Abbe made applications of radium bromide, of fifteen minutes each, to warts on the hands of two of the physicians present. One of these had lasted for twenty years, persisting in spite of various forms of treatment.

**The Modern Treatment of Bone Tuberculosis.** Dr. REGINALD H. SAVRE read a paper on this sub-

ject. Having remarked that the scientific treatment of any disease must rest upon a clear understanding of its aetiology and pathology, he referred to the complete eradication by operation of tuberculous foci advocated by many surgeons before the natural history of tuberculosis was as well understood as at the present day, and said that in still earlier times the opinion had prevailed that noninterference was advisable in bone tuberculosis. The proper mode of treatment lay between these two extremes, for, while the good results noted from this course had been arrived at empirically, recent laboratory investigation had shown the scientific basis for the facts which were observed clinically.

The speaker dwelt for some time on the causation, course, pathological characteristics, and clinical history of bone tuberculosis, and emphasized the prime importance of early diagnosis. To this end it was requisite that the patient should be stripped, and if disease was suspected in the hip, knee, or ankle, both sides should be examined thoroughly. If there was any doubt as to the presence of disease in a joint, it was a great mistake to resort to an anæsthetic in making the examination, as this would take away the most reliable guide we possessed for the diagnosis of early inflammation, namely, the involuntary muscular spasm by which Nature protected the joints from traumatism. Almost the first symptom to be manifested in joint inflammation was spasm of the muscles controlling the joint, and it was one of the last symptoms to subside. In the course of his remarks on diagnosis he referred to the use of tuberculin, and said that as yet but little had been reported as to the reliability of this test.

(To be concluded.)

## Letters to the Editors.

### AN IMPOSTOR.

234 CLINTON STREET, BROOKLYN, N. Y., April 28, 1908.

To the Editors:

On Thursday of last week a young man of good appearance called on me and made the following statement: That he was a graduate in medicine of Berne; that he had come to this country to practise medicine, but without success, and that he was in distress, having a wife and child to support; that through the efforts of Dr. Carl Beck, of Manhattan, and Dr. Wunderlich, of Brooklyn, he was receiving some aid from the German Medical Society. He gave his name as Eschenbach and begged me to get him into a hospital in any capacity. I called up the superintendent of the Kings County Hospital and stated the case, and was told to send the man to the hospital with a card of identification and he would be given a place as orderly. He never applied for the place. He does not live at the address he gave me. Dr. Beck and Dr. Wunderlich both repudiate him, and he is evidently an impostor. I have been informed, however, that he is using the card of identification from me as an introduction, and on the strength of this and some stationery which he stole from my office is gaining admission to the offices of physicians for begging purposes. I hereby repudiate him.

A. T. BRISTOW.

## MICROORGANISMS OR ARTIFACTS?

256 WEST FIFTY-SEVENTH STREET,  
NEW YORK, April 25, 1908.

To the Editors:

In to-day's issue of the *Journal* Dr. LeRoy describes some forms that he considers to bear an ætiological relation to psoriasis. In them I recognize appearances described by me in the *Journal* in 1872 (June and July) as being found when vaccine crusts and crusts from impetigo contagiosa were soaked in an alkaline caustic solution, that of sodium hydrate, six per cent., being perhaps the best. Later I verified Lang's observations in relation to psoriasis. At first I considered these forms to be fungoid bodies, but later became satisfied that they were simply artifacts and not bearing any ætiological relation to psoriasis or any other disease.

HENRY G. PIFFARD.

### Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

*Principles and Application of Local Treatment in Diseases of the Skin.* By L. DUNCAN BULKLEY, A. M., M. D., Physician to the New York Skin and Cancer Hospital, etc. New York: Rehnman Company. Pp. xii-130. (Price, \$7.)

Dr. Bulkley's vast experience in dermatology and his well known conservatism will cause this small and convenient book to meet with an unusually cordial welcome from the medical profession of the English speaking world. In it the topical forms of treatment recommended are fully reasoned out, but the reader is not burdened with prolix essays. The book is the product of Dr. Bulkley's personal observation, not a rehash of others' dicta, and that is always a great advantage in a work on such a practical subject as the treatment of disease. We can commend it without the slightest reservation.

*Comparative Electrophysiology.* A Physicophysiological Study. By JAGADIS CHUNDER BOSE, M. A., D. Sc., Professor, Presidency College, Calcutta. With Illustrations. New York, Bombay, and Calcutta: Longmans, Green, & Co., 1907. Pp. 760.

Since the appearance of Biedermann's monumental work on electrical phenomena as manifested in living organisms nothing has appeared in this field of research that is so interesting or so fundamental as the work before us.

The present volume, the author tells us, is the conclusion of a line of investigation of responsive phenomena, begun in 1900, to bear out the general thesis that living and inorganic substances show similarities of response, due to fundamental molecular reactions common to all matter in general.

He tells us that "an interesting link between the response given by inorganic substances and the animal tissues is that given by plant tissues." By methods which he has described in an earlier thesis he has been able to obtain from plants strong electrical responses to mechanical stimuli; such responses are known for the sensitive plants, but Bose shows them to be universal. Effects of fatigue, of temperature, of poisoning, and of stimulation of plants show their

electrical responses. Such findings as these have been regarded as highly improbable, and numberless controversial discussions were aroused at the time of their earliest publication. They are now accepted as facts. In this connection it may be recalled to the minds of our readers that there are many doubting Thomases in our ranks who are skeptical as to the facts concerning electrical registration of emotional states, etc., as recently studied by Jung and others.

The author was led to seek for the more intimate nature of these responses in a later investigation, published in 1906, where he found that the internal stimulus was in reality derived from some external source which was immediate or held latent in the plant tissues. Thus the blow of external stimulus is conserved in the plant tissues, and our wonder at the seeming disproportion of reaction to an apparently infinitesimal stimulus receives an explanation. That this fact may have some bearing on the high potential motor discharges in epilepsy, etc., is an inevitable association in the mind of the reviewer.

From this idea alone it becomes apparent that the comparative method of study for the elucidation of the complex biological problems of electrical energy in living matter is of the highest value, and Bose's work is worthy of a place in every investigator's laboratory.

We cannot at this time analyze the contents of this large work of over 700 pages. It is compact experiment and deduction, but a few points on which the author differs with current beliefs may be touched upon. The reactions of diverse tissues have heretofore been regarded as specifically different. As against this, a continuity has here been shown to exist between them. Thus, nerve was universally regarded as typically nonmotile; its responses were believed to be characteristically different from those of muscle. He has been able to show, however, that nerve is not only indisputably motor, but also that the investigation of its response by the mechanical method is capable of greater delicacy and freedom from error than the electrical. It has further been thought that plants are devoid of the power to conduct true excitation. This Bose shows to be incorrect.

He further pays his compliments to Pflüger's law of the polar effects of currents. This law, which has been held to be universal, Bose disputes, showing that both below and above certain limits of electromotive intensity the polar effects of currents are precisely opposite to those enunciated by Pflüger.

The work, as has been said, is one to be most highly commended; it is stimulating, profound, and full of suggestions of great practical value for the student of electrical phenomena as manifested in living matter.

*Hematological Atlas.* With a Description of the Technique of Blood Examination. By Priv. Doz. Dr. KARL SCHLEIP, Scientific Assistant in the Medical Clinic University of Freiburg i/B. English Adaptation of the Text by FREDERIC E. SONDERN, M. D., Professor of Clinical Pathology, New York Postgraduate Medical School and Hospital, etc. With Seventy-one Colored Illustrations. New York: Rehnman Company, 1908. Pp. 256 (Price, \$10.)

This handsome volume is equally creditable to the author, the translator, and the publisher. Its most striking feature is the excellence and accuracy of

the beautifully executed plates, drawn to scale and faithfully reproducing in color the well stained specimens which served as originals. Each illustration is separately mounted. In the accompanying text are fully described recent and practical methods for making blood films, the examination of fresh and dried specimens, staining, the estimation of hæmoglobin and specific gravity, the enumeration of the red and white cells, and the differential count of leucocytes. Every type of the essential blood diseases is adequately shown, also the changes associated with tumors of the bone marrow and the parasitology of the blood, including malarial disease and trypanosomiasis. An effort has been made in every case to present a simple technique which will serve as a reliable guide to the physician interested in clinical pathology, as well as for the more experienced laboratory worker. This atlas of hæmatology meets a real want and will prove, we believe, as indispensable to the clinical microscopist as are colored plates and wax models in the study of dermatology. The work is also notable as a fine specimen of artistic book-making.

### Public Health and Marine Hospital Service:

*Official list of changes of stations and duties of commissioned officers of the United States Public Health and Marine Hospital Service for the seven days ending April 25, 1908:*

- ALTREE, G. H., Acting Assistant Surgeon. Granted leave of absence for thirty days, from May 5, 1908.
- BAILEY, C. A., Acting Assistant Surgeon. Directed to proceed from St. John, New Brunswick, to Quebec, Canada, for duty.
- BROOKS, S. D., Surgeon. Granted leave of absence for three days, from April 20, 1908.
- BROWN, S. E., Acting Assistant Surgeon. Leave of absence granted for fourteen days, from March 15, 1908, revoked.
- FOSTER, S. B., Acting Assistant Surgeon. Leave of absence granted for fifteen days, from April 6, 1908, revoked; granted leave of absence for seven days, from April 13, 1908.
- HAMILTON, J. H., Acting Assistant Surgeon. Granted leave of absence for two days, from April 20, 1908.
- HOLT, J. M., Passed Assistant Surgeon. Granted leave of absence for seven days, from April 21, 1908.
- SIMONSON, J. H., Acting Assistant Surgeon. Granted leave of absence for two days, revoked.
- SMALL, E. M., Acting Assistant Surgeon. Granted leave of absence for eight days, from April 18, 1908.

#### Boards Convened.

Boards of medical officers were convened to meet on April 27, 1908, for the purpose of examining candidates for the position of cadetship in the Revenue Cutter Service, as follows:

- Baltimore, Md.: Surgeon L. L. Williams, chairman; Assistant Surgeon H. H. Warner, recorder.
- Boston, Mass.: Surgeon R. M. Woodward, chairman; Assistant Surgeon T. W. Salmon, recorder.
- Chicago, Ill.: Surgeon G. B. Young, chairman; Passed Assistant Surgeon J. S. Boggess, recorder.
- Detroit, Mich.: Surgeon Fairfax Irwin, chairman; Passed Assistant Surgeon M. J. White, recorder.
- Galveston, Tex.: Passed Assistant Surgeon G. M. Corput, chairman; Acting Assistant Surgeon W. H. Gammon, recorder.
- Mobile, Ala.: Surgeon G. M. Guiteras, chairman; Acting Assistant Surgeon J. O. Rush, recorder.
- Newport News, Va.: Assistant Surgeon G. L. Collins, chairman; Acting Assistant Surgeon A. C. Jones, recorder.
- New York, N. Y.: Passed Assistant Surgeon J. A. Hydegger, chairman; Acting Assistant Surgeon F. Mahoney, recorder.
- Philadelphia, Pa.: Surgeon J. M. Gassaway, chairman; Passed Assistant Surgeon Taliaferro Clark, recorder.
- Portland, Me.: Surgeon W. P. McIntosh, chairman; Acting Assistant Surgeon A. F. Stuart, recorder.
- San Francisco, Cal.: Surgeon H. W. Austin, chairman; Passed Assistant Surgeon C. H. Gardner, recorder.
- Seattle, Wash.: Passed Assistant Surgeon M. W. Glover, chairman; Assistant Surgeon C. W. Chapin, recorder.
- Washington, D. C.: Assistant Surgeon General W. J. Pettus, chairman; Passed Assistant Surgeon J. W. Trask, recorder.

### Army Intelligence:

*Official list of changes in the stations and duties of officers serving in the medical department of the United States Army for the week ending April 25, 1908:*

- CLARK, J. A., Captain and Assistant Surgeon. Ordered to Madison Barracks, N. Y., for temporary duty.
- DAVIS, W. R., Captain and Assistant Surgeon. Ordered to accompany troops from San Francisco, Cal., to Fort Thomas, Ky., and return; granted leave of absence for fifteen days.
- DELOFFRE, S. M., Captain and Assistant Surgeon. Ordered to Columbus Barracks, Ohio, for duty; advanced to grade of captain to rank from September 10, 1908.
- GREENLEAF, H. S., Captain and Assistant Surgeon. Ordered to duty at Madison Barracks, N. Y., at the expiration of his present leave of absence.

HARRIS, H. S. T., Major and Surgeon. Granted an extension of one month to his leave of absence.

KENDALL, W. B., Major and Surgeon. Granted leave of absence for one month, about April 20.

SCHREINER, E. R., Major and Surgeon. Returned to duty at Army General Hospital, San Francisco, Cal., from detached service to Madison Barracks, N. Y., and leave of absence.

### Navy Intelligence:

*Official list of changes in the medical corps of the United States Navy for the week ending April 26, 1908:*

- BAKER, M. D., Pharmacist. Appointed a pharmacist from April 17, 1908.
- FISKE, C. N., Passed Assistant Surgeon. Orders to Washington, D. C., revoked; to continue treatment at the Naval Hospital, Mare Island, Cal.; ordered home and granted sick leave for two months, when discharged from treatment at the Naval Hospital, Mare Island, Cal.
- KOLTES, F. X., Assistant Surgeon. Detached from the navy yard, Mare Island, Cal., and ordered to the *Connecticut*.
- RANSELL, R. C., Assistant Surgeon. Detached from the *Connecticut* and ordered to the second torpedo flotilla.
- ZIEGLER, J. G., Acting Assistant Surgeon. Ordered to duty at the Naval Hospital, Portsmouth, N. H.

## Births, Marriages, and Deaths.

#### Born.

USHER.—In Camp Stotsenburg, Philippine Islands, on Friday, January 17th, to Dr. Francis M. C. Usher, United States Army, and Mrs. Usher, a son.

WHALEY.—In Fort Sam Houston, Texas, on Tuesday, April 7th, to Dr. Arthur M. Whaley, United States Army, and Mrs. Whaley, a daughter.

#### Married.

BUCK—WHITE.—In Camp McKinley, Philippine Islands, on Friday, April 10th, Dr. Carroll D. Buck, United States Army, and Mrs. Ynez Shorb-White.

HILL—CLAY.—In Atlantic City, New Jersey, on Wednesday, April 29th, Dr. Howard Kennedy Hill and Miss Ruth Clay.

MASON—STRICKLAND.—In San Francisco, California, on Wednesday, April 15th, Dr. William McPherson Mason and Miss Geraldine Belle Strickland.

ROBERTSON—BROWN.—In Boulder, Colorado, on Tuesday, April 14th, Dr. Eugene H. Robertson and Miss Elinore A. Brown.

SCHUMAN—PEIGHTOL.—In Philadelphia, on Thursday, April 16th, Dr. Frank L. Schuman, of Huntington, Pennsylvania, and Miss Mary Peightol.

#### Died.

CONOVER.—In Port Townsend, Washington, on Sunday, April 19th, Dr. Simon B. Conover.

GAMBLE.—In Gastonville, Pennsylvania, on Tuesday, April 14th, Dr. William Jackson Gamble.

LEGLER.—In Oakland, California, on Tuesday, April 14th, Dr. Henry T. Legler, aged eighty-nine years.

MOORE.—In San Antonio, Texas, on Tuesday, April 14th, Dr. Frank P. Moore, aged fifty-seven years.

PATTERSON.—In Cincinnati, on Friday, April 17th, Dr. William G. Patterson, aged ninety-three years.

ROSS.—In Münster, Westphalia, Germany, on Wednesday, April 15th, Dr. Joseph B. Ross, of St. Louis, Missouri, aged fifty years.

STANSFIELD.—In San Francisco, California, on Wednesday, April 15th, Dr. Halstead A. Stansfield.

STEBBINS.—In Omaha, Nebraska, on Sunday, April 19th, Dr. Richard Stebbins, aged eighty-four years.

STEPHENSON.—In Iroquois, Ontario, Canada, on Monday, April 13th, Dr. James Stephenson, aged seventy-three years.

THOMAS.—In Cleveland, Ohio, on Saturday, April 18th, Dr. William E. Thomas, aged eighty years.

TOWNE.—In Essex, Massachusetts, on Thursday, April 16th, Dr. Charles J. Towne.

WILDER.—In Medfield, Massachusetts, on Friday, April 17th, Dr. Ralph Wilder, aged thirty years.

WRIGHT.—In Montreal, Canada, on Friday, April 17th, Dr. William Wright, aged sixty-one years.

#### THE RESTORATION OF THE NORMAL BALANCE OF THE FOOT.

##### I.

*A Preliminary Paper. The Anatomy and Functions of the So Called Arch of the Foot, with Results of Experiments on Both the Normal and the Weak Foot.*

By E. G. ABBOTT, M. D., AND H. A. PINGREE, M. D.,  
Portland, Me.

The term "arch," as applied to that part of a normal foot which does not come in contact with the surface beneath it, when a person is standing, appears to be a misnomer and most misleading. "Dome" or "vault" would be a far more descriptive word to use, and "arch" would be a better term to apply to any line extending over the surface of the dome from one point to another. Changes in anatomical nomenclature are, however, not readily accepted, therefore no attempt will be made to substitute either of the terms suggested; but the reader is requested to bear in mind that wherever "arch" occurs in the phraseology it represents that part of the foot which as a whole is dome shaped.

In the description of the arch of the foot it has been customary to consider it as half of an arch

taken of this rather than of the living subject, it would be readily seen that the usual impression is erroneous, and that, when the two feet are placed in apposition, it would be more correct to describe the contour of the surfaces, which do not come in contact with the floor beneath them, as two separate arches (Fig. 2), or speaking more accurately, as a segment of two arches; and, if the space beneath the skeletal feet held in this manner is filled with plaster of Paris, instead of our having an object similar in shape to one shallow bowl, we would

FIG. 1.—Diagrammatic cross section of arches with skeletal foot in apposition.

have an object which more closely resembles two bowls (Fig. 3).

It would seem then more exact to describe the arches of the feet separately, and to represent each as a section of a shallow bowl, that portion being cut off which extends beyond the internal border of the foot, but along a line, which by no means corresponds to its highest part. A plaster cast of the skeleton of the foot would show that the highest part of the model is not the inner border, but that it is some distance external to it.

If, beginning at the distal end, we draw a line (Fig. 4) longitudinally over the surface of the highest part of the arch of the skeletal foot, we shall find that it passes over the third metatarsal bone, the external cuneiform, outer part of the scaphoid, the astragalus and the inner margin of the calcaneum; and that all parts internal to this line, consisting of the first and second metatarsal bones, middle and internal cuneiform, a large part of the scaphoid, and a part of the astragalus, as well as those external, the fourth and fifth metatarsal bones, cuboid and calcaneum, are placed on lower planes.

A cross section of the plaster cast near its centre (Fig. 5) shows the arch well defined transversely, its external end, however, on a much lower level than its internal, and its crown at a point near the junction of the middle and inner thirds. The other parts of the foot usually mentioned in descriptions—the anterior metatarsal arch, and the arch formed by the internal border of the foot—are not of so much importance, and their consideration is not so necessary, if we thoroughly understand the arch of the foot as dome or vault shaped, for, if this arch is maintained within its normal limits of motion, the other parts will remain in their normal position.

When the foot is used as a support, the arch is

FIG. 2.—Plaster cast of the arch of the skeletal foot.  
FIG. 3.—Plaster cast of the arch of two skeletal feet held in apposition.

formed by placing the inner borders of the feet in apposition. It is also usual to regard a point situated on a line between the feet thus placed as the highest part. If the skeleton of the foot is used for this demonstration, and a plaster cast (Fig. 1)

held in place by muscles, fascia, and ligaments; but there is very little strain on any of these parts, as the arch is so constructed that in a normal condition the balance of the foot is easily maintained. The

arch is normally somewhat depressed, when the foot is used only as a support, but this change is not great. It is simply a relaxation from muscle contraction, and the muscles then serve as strong ligaments in conjunction with the ligaments proper to maintain the arch of the foot. The curve of the internal border of the foot is also somewhat lessened by this relaxation, but not to any considerable extent.

The usual eversion of the foot in this state of support (Fig. 6) must not be mistaken for a pronated foot in the sense of a

deformity, as this position is caused chiefly by a rotation of the femur to relieve the strain upon the hip structures; and all the normal depression of the arch would take place just the same if the foot was inverted. In some instances it appears that the arch is normal in shape although the foot is habitually abducted, and the inner border is bulged (Fig. 7); yet the only way to change this habitual abduction or pronation is to increase the height of the arch, and, when this is done, the bulging of the inner border disappears and the foot returns to a corrected position (Fig. 8); therefore, what might seem to be a normal arch in a foot which is habitually abducted is not so for that individual, for, when it is raised, the deformity disappears.

In activity the foot is controlled by muscles, and as long as they are in a normal condition and noth-

(flexed and extended) by muscular action to a certain extent in the normal foot, and, with this raising and lowering, the foot is changed from adduction to abduction and vice versa. It is a compound

FIG. 4.—Line indicating highest part of arch at different points.

FIG. 6.—Normal attitude of rest, showing outward rotation of limbs without pronation.

movement, and must necessarily be so on account of the shape and structure of the arch; and the primary changes, which have been mentioned, cannot take place alone.

In the preservation of the normal arch movement it is necessary to take into consideration only those

centre.

ing interferes with the joint motion, the foot performs its functions in a normal manner. The principal movements which may take place in the arch of the foot are four, flexion, extension, adduction, and abduction. The arch is raised and lowered

FIG. 8.—Pronated foot with bulge on inner border. Arch is raised and no bulge.  
FIG. 9.—Same foot as Fig. 7, arch raised to normal height by a wedge. Bulge and bulge on inner border disappears.

muscles which control these movements. The principal muscles which raise the arch (flex and adduct) are the anterior and posterior tibial, the latter having the greater influence, as it is much more power-

FIG. 9.—Showing inability to raise arch by traction on tendons of anterior and posterior tibials when heel cord is short. In Fig. 10, arch easily raised after heel cord has been severed.

ful. The chief ones which enter into any depression of it (extend and abduct) are the peroneus longus, brevis, tertius, and gastrocnemius. All the other muscles which participate in any way in these movements are only adjuncts to these, and alone exert very little control.

The following experiments, which were performed upon recent amputations with the assistance of Dr. F. A. Bartlett, illustrate the changes which occur in the arch of the foot when the muscles are severed, the amount of traction requisite to maintain the arch in a normal position, and the amount necessary to raise it to a normal position, when depressed; also an experiment upon the living subject showing the alterations in the arch of a weak foot when it is changed from the position of rest to that of pronation.

*Experiment I.* Cadaver. Showing the effect of a much shortened heel cord upon the arch of the foot. If a dissected weak foot, in which the heel cord is shortened, is held in the same position as that of the normal foot in use (all restriction except the short heel cord being absent), it will be found that it is impossible to raise the arch by traction upon the anterior and posterior tibial muscles to a

normal position (Fig. 9) ; but, if the tendo Achillis is divided, that the inner border of the foot is raised easily to the desired height (Fig. 10).

*Experiment II.* Cadaver. Showing the effect of the peroneus longus and brevis, when they are shortened, upon habitual abduction of the weak foot. If a weak foot, which is habitually abducted, is prepared in the same manner as in Experiment I, and if force is applied in an attempt to adduct it, it will be found that there is no change in the altered arch, and that it is impossible to bring the foot into a normal position (Fig. 11). If, however, a tenotomy is placed beneath the shortened tendons and the same force applied, the foot will, when the tendons are severed, readily assume the adducted position (Fig. 12).

*Experiment III.* Cadaver. Showing the effect in a weak foot of dividing the tendo Achillis, the

FIG. 10.—Showing effect of the tenotomy of the tendons of the peroneus longus and brevis, when the tendo Achillis is cut. FIG. 11.—Same foot as in Fig. 10, arch easily raised by same traction when peroneus is cut.

tendons of the peroneus longus and brevis, and of shortening the tendons of the anterior and posterior tibial muscles. If, having dissected the skin and subcutaneous tissues from the foot and ankle in a case of weak foot with permanent pronation, we use force in the direction of adduction, it will be found impossible to bring the foot into a corrected position (Fig. 13), but if the tendo Achillis and the tendons of the peroneus longus and brevis are cut, the foot swings readily into the desired position, and, if the tendons of the anterior and posterior tibial muscles

are shortened, it remains in this position (Fig. 14).

*Experiment IV.* Cadaver. Showing the neces-

FIG. 13.—Arch held depressed by short heel cord and peronei.

sary amount of traction on the posterior tibial muscle in order to maintain the arch of the foot when it is in normal position. A normal foot, having been

FIG. 14.—Same foot as in Fig. 13, with peronei and heel cord short, and the foot brought to normal position.

prepared by removing the skin and subcutaneous tissues, is placed in the position of weight bearing. All the parts which hold the arch are divided so

that when a light weight is placed upon the leg the foot will assume the pronated position, with the internal border resting upon the surface beneath it (Fig. 15). Now, if scales fastened to a pulley overhead are hooked into the cut end of the posterior tibial tendon, and if the arch is pulled into normal position (Fig. 16), it will be found that a traction of twenty-four pounds will maintain a normal arch when a weight of two hundred pounds is placed on the upper end of the tibia. This experiment would indicate that, in order to hold the arch in position, the power applied to one of the muscle tendons, which normally supports the greater part of the strain in weight bearing, would need to

FIG. 15.—All parts divided which hold the arch in normal position, allowing the inner border of the foot to rest upon the surface beneath it.

FIG. 16.—Same foot as in Fig. 15, showing that a traction of 24 lbs. applied to the posterior tibial tendon, will maintain the arch in normal position, when a weight of 200 lbs. is placed upon the leg.

be less than one eighth of the weight supported. Therefore, if the arch is in normal position, it requires very little muscular power to maintain it.

*Experiment V.* Cadaver. Showing the same experiment with the tendon of the anterior tibial muscle fastened to the scale in conjunction with the posterior tibial (Fig. 17). In this experiment it requires only nineteen pounds to hold the arch in position. This shows the advantage in having the two tendons pull together, in that the amount of traction necessary is lessened about one fourth.

*Experiment VI.* Cadaver. Same specimen used as in Experiments IV and V. Showing the amount of traction necessary to raise the depressed arch when applied with the foot fully pronated. If the leg is held erect and the foot allowed to pronate so

that the internal border will come in contact with the surface beneath, and if traction is then applied to the free ends of the anterior and posterior tibial tendons (Fig. 18), it will be found that, in order to lift the arch, an amount of force equal to the weight borne upon the leg is required, and if two hundred pounds are placed on the upper end of the tibia, it will take a force equal to two hundred pounds on the scales to raise the arch from the surface upon which it rests, but that this amount of force lessens proportionately as the foot approaches its normal position.

*Experiment VII.* Living subject. Showing the change which takes place in the arch of the weak foot at rest, when it is pulled by muscular action into the pronated position. If a person with a weak foot is placed in a sitting posture, with the legs crossed, the foot being suspended free in front of

let the patient place the foot in a position of extreme pronation, and it will be seen that there is a marked difference between the planes of the two pieces of wood (Fig. 21).

Any change from the normal in the structure and

FIG. 19.—Weak foot at rest. A. Arch apparently normal. Same foot pronated with arch increased, due to action of peroneus longus in lowering the first metatarsal bone.

function of the foot to the pathological of the weak foot must come through a disturbance of the arch, and as long as the arch is maintained such a condition as weak or flat foot cannot take place. Therefore, in examining a weak or flat foot, it is necessary to consider only the arch and those structures which should control and maintain it, for, if the arch is restored, and those parts which hold it in position regain their functions, the foot will recover its normal condition. The normal state of the arch and the parts which maintain and control it are then of primary importance, and any pathological condition, like that found in weak foot, is due to some change in these structures.

In looking at the anatomy of the weak or flat foot

FIG. 20.—Weak foot at rest. A. Arch apparently normal with heel and ball on same plane.

we find that the changes which have taken place are many, but that those which prevent the normal maintenance of the arch after all restriction to passive motion has been removed are of the most concern. The pathological alterations in the individual ligaments, bones, and joints are of little im-

FIG. 17.—Same foot as in Fig. 16, with the addition of the anterior tibial the amount of traction is reduced to 10 lbs.  
FIG. 18.—Same foot as in Fig. 17, 200 lbs. weight placed upon the leg with arch depressed. 200 lbs. traction upon the anterior and posterior tibial tendons is required to start arch from surface beneath it.

him, it will be seen that the arch of the foot is apparently normal in height (Fig. 19). Now, if the patient is requested to hold the foot in extreme pronation, the arch will still seem to be of normal height or even higher, but if a more careful observation is made, it will be seen that the arch is not so high, but that it is twisted, and that the apparent increase is due to the pulling of the peroneus longus muscle upon the first metatarsal bone, which, even in the normal foot, is freely movable, and may be lowered easily one half an inch by this action.

A more striking method of demonstrating this twist is to fasten two strips of wood across the bottom of the foot, one under the heel and the other beneath the ball, so that they will both be on the same plane when the foot is at rest (Fig. 20); then

portance in this connection, as they are only incidental to the continued depression of the arch. It matters not in what condition we find the foot, it must first be brought to such a state that it is freely movable in all directions, i. e., to a condition of weak foot.

The next step or change from a weak to a normal foot presents a far more difficult problem to solve;

FIG. 21.—Weak foot pronated. Arch apparently normal, but twisted by action of peroneus longus on first metatarsal bone.

therefore, the changes which take place in the joints and ligaments, in so far as they retard motion, may be left out of consideration, and attention given to those parts which, through their pathological changes, prevent a weak foot from being a normal one, namely, the ligaments and muscles. The ligaments are lax throughout the whole structure, and those muscles which control certain motions are lengthened, while others are shortened. On the inner side of the foot the anterior and posterior tibials are the principal muscles at fault. They are stretched much beyond their normal limit; are pulling at a great disadvantage whenever the foot is in use, and give no support when the foot is at rest. On the outer side of the foot the peronei are found to be shortened and often displaced; but, instead of being weakened in their action, both as a support and as a lever, they are strengthened through this displacement, and work most advantageously in increasing the deformity. It is not unusual to find the heel cord shortened sufficiently to prevent the calcaneum from being held at its normal angle, thereby restraining the arch of the foot from preserving its normal contour when the foot is flexed. The plantar fascia, the principal truss of the arch, is stretched and gives little aid in holding the foot in position.

#### DEFECTIVE VISION AND THE MENTALLY SUB-NORMAL CHILD.\*

By S. W. NEWMAYER, M. D.,  
Philadelphia,

Assistant Ophthalmologist to the Polyclinic Hospital.

This article has been written, not to enlighten the ophthalmologist or that small part of the medical profession who are acquainted with diseases of the eyes, but to arouse in the general practitioner a greater interest in his responsibility to school children suffering from defective vision. I have tried to express myself in terms which would make the

subject likewise clear to such laymen as teachers and educational authorities, who should have a knowledge of this subject. Another important object of this article is to try to correct a dangerous misuse or abuse of the "test card," not only by laymen but by some of the medical profession.

In recent years much has been written and said in reference to the relation of physical defects and mentality. Several prominent physicians have asserted that physical defects have no influence on mentality. This may oftentimes be considered correct if they refer to that mental deficiency which is of such a degree to classify the child as an idiot or imbecile. It seems to me that the varied opinions are due to the too loose use of the term "mentally defective." I believe this term should be reserved for those graver cases which are due to congenital defects of the brain and its functions, to those cases which from birth show little or no development of their mental faculties. To those minor cases which exhibit an abnormality to a moderate degree, whether inherited or acquired through physical defects, the term "mentally subnormal" could be applied. The use of such a classification may facilitate a more systematic and uniform study of this important medicopsychological subject. Considering the mentally subnormal, I am convinced that physical defects are an important factor in their study. It is true that not every child with a physical defect is mentally subnormal, because the same defect influences each child differently.

There should be an attempt to show the relation between cause and effect. In the study of each individual case, it is not only necessary to isolate if possible the causative factor, but the individual reaction to such cause. One child may not be affected by a moderate degree of defective vision, and another child be seriously hampered by the same amount of defect. Most physicians have seen cases of decided change in mentality following an acute disease such as grippe or typhoid fever. This may or may not be due to the lowered vitality. It may be due to the effect of the toxins directly on the brain. There may be as a sequela a defect of hearing or of vision. However, most physicians will agree that some physical defects can cause an altered condition in the mental state. The important problem is to recognize these defects, and correct them.

The time is near when our public school authorities will recognize and classify in a practical manner the children with varying degrees of mentality. At present the child with little physical vigor and lessened mental capacity is placed in classes with far brighter pupils, and is goaded on to keep the pace with the most precocious child. These backwards are overlooked and misinterpreted, and sooner or later are physical or mental wrecks. If we could only follow these cases after school life we would find some interesting statistics of terminations. The majority of these cases leave the schools, no matter to which grade they have reached, as soon as they pass the age of thirteen or fourteen years, and out of reach of the "Truant Law." These are the children that must make undesirable citizens. They have not the education to take skilled positions, the greater time idle, and

\*Read before the American Medical Association.

easily led into a life of waywardness. The termination is oftentimes the prison or asylum. The noble type of teacher is she who recognizes such un-

FIG. 1.—A case of convergent squint in a school child, due to defective vision.

fortunates in her class, and makes every effort to discover a cause, and attempt to have it corrected.

Let us consider the various physical defects which may be found in children and study their effect on the mentality. Acquired orthopædic defect, whether spinal curvature or hip disease, etc., have no direct action on the brain or its functions, as likewise congenital defects unless accompanied by a congenital or hereditary defect in the brain itself. Lesions of the skin, nose, and throat (including the much talked of adenoids) exercise no retardation of the mental faculties, except in those cases where these defects affect the general health and nutrition of the child. These are sometimes cases of fatigue or exhaustion, and from whatsoever cause the existence of these symptoms may cause a mental subnormality.

The nervous system with its allied diseases is an important factor in causing mental subnormality.

FIG. 2.—A child wearing convex lenses, with one convergent squint and the other, an oblique.

However, in most of these cases the nervous symptoms are secondary to another defect. Not infrequently in children this defect is in the eyes. The eyes and ears are the remaining organs, defects of

which may cause mental retardation. Normal hearing is important to normal mental faculties, but when one considers that there are few impressions dependent on the sense of hearing, that can not be conveyed by the sense of sight, and also the relative infrequency of defective hearing in comparison to defects of vision, a study of the eye and its defects is by far the most important. I believe I am not far from correct when I make the assertion that more than seventy-five per cent. of the cases of mental retardation are due to, 1, disease of the brain, with a greater or less degree of absent or undeveloped, untrained, latent function; and, 2, defects and diseases of the eyes.

When we consider the practical application of these two great classes with an attempt at treatment, the mentally defective of the type of imbecile or idiot, and due to inherited or congenital absence of brain function, is a hopeless patient and should be placed where he does the least harm to society and himself. The patient with the undeveloped, untrained, latent faculties can oftentimes be benefited by a proper systematic training. The eye, defects of which cause a large percentage of cases of mental subnormality, is most often amenable to treatment, but often overlooked as the offending organ. The chief reason for not suspecting the eyes as the seat of trouble is that the examiner always expects to find symptoms and signs to point to the eyes, forgetting that oftentimes gross changes may be present in these organs and no outward signs noticeable. There may be no redness or inflammation of the lids, no squint, no apparent impairment of vision, possibly only an occasional headache, twitching of the lids, or possibly a sty, and considerable abnormality present. Never exclude the eyes except in the proved absence of ocular disease, the most thorough and systematic examination for possible errors of refraction, or abnormalities of binocular vision. It appears that much of the deception is due to an abuse of the test card. These cards seem to be used for absolute diagnosis of eye defects, instead of a valuable aid to confirm the findings by instruments of precision.

FIG. 3.—Test card for children and adults, according to the author.

Much time and energy have been wasted in gather-

believe there is no better method of detecting these cases among school children than the observing and interested teacher. She can tell more by her continuous close contact and watching the actions of the children than anyone who stands the child for a few minutes before a test card. A child may at that moment have acute vision, but at some time while at work in the class room show the effects of eyestrain.

Why do the same errors in different people not produce the same signs, symptoms, and ultimate effects? One is apparently unaffected, another suffers from headache and a train of reflex symptoms sufficient to cause invalidism. There may be violent attacks of headache; dull or sharp pains in the eyes; sore and inflamed eyelids; twitchings of the forehead or eyes resembling chorea; a marked squint; there may be convulsions, and again there may be few symptoms. Sometimes there may exist only a continuous dulness and inability to work or absorb any knowledge. These variations depend much on the temperament of the individual; one is phlegmatic, another is neurotic.

To obtain a normal education a child must obtain correct impressions, and to this end normal vision is necessary. Every child with errors of refraction is not a mental defective, but the pupil who suffers from defective vision remaining uncorrected must be below the mental status of another child of equal abilities who is not handicapped by such a disability. The pupil with defective vision, especially if symptoms are present, must be below par, and hence mentally subnormal. The true keenness and intelligence of the pupil may still be evident, but the education nevertheless is hindered in various ways. Headaches may make the child restless and inattentive, or there may be for the same reasons repeated absence from school. Every child who seems mentally subnormal, or who suffers from headaches, nervousness, blurring or impaired vision, facial twitchings, or frequently inflamed eyes, should be thoroughly and systematically examined by a competent ophthalmologist for possible refractive errors, and deviations from normal binocular vision.

Beyond the correction of errors of refraction, many physicians seem to place little importance on the muscles attached to the eyes and keeping a perfect binocular vision. If a self evident squint is not present, this important factor is oftentimes overlooked. A muscle unbalance of these organs may give symptoms sufficient to disable a patient. As to the cases of squint so often met in school children, they are generally dependent on gross errors of refraction, mainly hypermetropia and hypermetropic astigmatism. One can safely say most of these children are greatly benefited if fitted with the proper glasses early enough. In some cases the eyes are completely straightened after wearing the proper correction. Fig. 1 shows a characteristic case of squint or strabismus found in a school child and due to refractive errors. It is evident how the presence of a squint may affect the education of a child.

How old should a child be to be examined for glasses? This question is frequently asked. If a child needs them badly, as shown by any prominent symptoms or a marked squint, I believe the child should be examined and supplied with glasses as

soon as it is able to sit on a chair. It is in early childhood before school days that the best results are obtained.

Here I would offer a word of advice to teachers. Children who have been wearing glasses should be watched, and if they come to school without them, should be sent home to bring them. If the child persists in not wearing the glasses, possibly the glasses are not suited, or the frames are so ill fitting as to give discomfort. Again it seems criminal to allow a child to sit in the class room wearing a pair of glasses so out of adjustment that one lens is on the forehead and the other upon the cheek. An example of such a case is shown in Fig. 2.

When a physician writes a prescription for glasses, and the lenses are supposed to contain cylinders at a certain axis, to correct astigmatism, what results can be expected from the glasses if the patient wears the lenses at any axis? The patient has poor results and the physician receives the blame. Again the proper fitting of the frames is as necessary as the proper lenses. Unless otherwise ordered for a certain effect lenses should be so adjusted that the centre of the lens is at the centre of the pupil. A little attention by teachers to children wearing glasses would result in giving considerable comfort. Frequently a patient returns after a year or so and asks whether they need to change their glasses, because they cannot see as clearly as they did at first, and on adjusting the lenses the fault is easily remedied.

Many parents pay little attention to their children who have squint, because they believe it to be a congenital condition for which little can be done. It may be well to impress on such parents that a congenital squint is rare. It oftentimes happens, however, that a child inherits defective vision, and through this defect the squint is manifested. When a squint is congenital, there is oftentimes an accompanying asymmetry of the orbits and possibly of the skull. It is stated by some that the asymmetry of the orbit admits of the eye turning to adjust itself to the shape of the orbit.

Teachers should aid the physicians in overcoming the opinion that "children should not wear glasses because in that event they must wear them forever." On the contrary they can assure the parents that oftentimes by correcting defects early in life, in a few years the eyes improve sufficiently to allow the child to discard the glasses.

Campaigns for improvements in questions of public health; if not backed by law, are a tedious and oftentimes a fruitless task. I therefore believe that "the State should not only protect its people from their own ignorance and superstitions in questions of public health, concerning contagious diseases like smallpox and diphtheria, but it should likewise pass a law which would compel every child before being enrolled in a public school, not only to undergo a physical examination, but any defect which would greatly interfere with that child from obtaining a normal education should be corrected before the child is admitted to school." The examination should include a thorough examination of the eyes, ears, nose, and throat by specialists in these branches.

I have advocated for several years that a procedure such as this would make unnecessary an annual examination of each child. This would also

allow the time of attending physicians free to be devoted to examinations of new pupils, and all acute cases which arise in the schools. A child with defective vision or hearing most often has the defects when it begins school life, and it is the exception that these conditions arise during this period. A child may have serious errors of vision, and the parents and child not notice them until the work at school makes apparent the defect. Sometimes the conditions in these cases are blamed on too close application in the school room, but it is not so.

It is interesting to note that recently the authorities in London passed a law similar to the one cited, and it went into effect January, 1908. Parliament has asked the Board of Education to present to them an annual report of the findings and results obtained. They intend later to create school dispensaries for diseases of the eyes and ears, etc. These clinics, besides a dental clinic, are already in vogue in some of the larger European cities.

Such recognition by the authorities of large cities is, in itself, sufficient proof of the views on relation of physical defects to mentality. A child in early school days may, because of a defect of vision, merely show an inability to acquire certain subjects, especially reading and writing, but later the child may, to a great extent, become incapacitated. These pupils oftentimes manifest an unaccountable stupidity, and their inattention and misconduct deprive both the teacher and the other pupils of concentration to work.

Modern scientific pedagogy looks to the physician to explain why this or that child is dull and mentally subnormal. Many physicians are content to merely label the child as a congenital mental defective. An exhaustive attempt to localize the trouble is ignored, and the teacher accepts the diagnosis of inferior brain function, and a hopeless case. This exonerates the teacher of all responsibility, and covers up her inability to instruct a pupil, which is not "an ordinary, every day, routine pupil."

It would be a great aid in the study of mentally subnormal children, if teachers would give us accurate records of the school work of pupils mentally subnormal and physically defective. The study should include the psychological study of the cases, the physiology of the child's various mental processes. A close study of the kind of work the child fails in, and any change in these branches after correction of defects, would aid in a study of relationship between physical defects and mentality.

The results obtained from the correction of eye defects are generally good, sometimes marvelous. The best results are obtained in the earliest school days. In older children, occasionally, defects of vision are found and corrected, and the results on the mental condition are not immediately apparent. Here the teacher or parent is too early discouraged. One must not forget that prolonged eye strain sets up pathological changes in the tissues of the eyes, and even after removal of the cause the results may still remain for some time.

The test card being the only instrument available for the examination of eyes by teachers and others not possessing the scientific knowledge of a physician, it may be well to explain how the best and most practical results can be obtained from them. Re-

cently a principal of a public school published the results of an examination of about five hundred children, using the ABC letter test card, and the illiterate E card, and compared the results. His method consisted of placing the child sixteen feet from the card; if he saw correctly the letters of the sixteen feet line, he was asked to step back two feet, and if he still read the letters correctly he was designated as farsighted. If he could not see distinctly every letter at sixteen feet, he was advanced two feet at a time until he accomplished the reading, and these cases were all labeled as myopic or near sighted. His results recorded were as follows: With ABC card: Near sighted, 65.8 per cent.; far sighted, 15.5 per cent. With the illiterate E card he found: Near sighted, 8.1 per cent.; far sighted, 82.2 per cent. Having obtained these directly opposite results, he very ingeniously formulated a theory to prove the illiterate E test card built wrong. It happens, however, that the results he obtained with the ABC card are nearer to being correct. Myopia in children is rare in comparison to hypermetropia, even if one does hear more about "the near sighted child." The principal comments as follows: "I frequently found it necessary in all grades, especially in the primary grades, to allow the pupils to rest their eyes. . . . Many eyes after reading a half dozen letters were filled with tears. . . . It was not an uncommon thing for a pupil to have to move up to twelve feet in order to make out the direction of the E; but having once clearly seen it he could recognize the other directions with apparent ease at twice the distance." It is not my intention to ridicule the work of this gentleman, but rather to congratulate him on his honesty in publishing such a full and concise report after obtaining such extremely opposite results. His comments spell most plainly *accommodation*. This principal is not the only one who has made the error of trying to tabulate the near and far sighted by means of the test cards. I recently read the report of a physician who examined one thousand school children and used the following method: The pupil was placed five metres from a test card, and a convex spherical lens of a half dioptre was placed in front of the eye; if the child said he saw better with this lens than with the naked eye he was registered as hypermetropic. If he saw better with a concave spherical lens of a half dioptre he was considered near sighted, and all others were normal. These statistics are worthless, as a child may easily overcome even a much stronger lens and see distinctly.

The test card is a valuable subjective test, but to a layman admits only of his diagnosing bad cases of defective vision. He can rarely with accuracy distinguish hyperopia, myopia, and astigmatism. He therefore can obtain most practical results by using the test card to choose the cases of defective vision, and then refer the case to a competent ophthalmologist to make an accurate diagnosis. After a case is examined the teacher would do well to follow the pupil, urging the parents to obtain the glasses. The test card is worth little more to the physician until he relaxes accommodation with a cycloplegic. Then the lenses which bring the visual acuity to normal are the proper correction. If there is no astigmatism, or the astigmatism is at an axis of 90° or 180° the physician

may be able to find the correcting lenses with no further objective tests than the test card and lenses. However, this method should only be used to confirm the findings by instruments of precision, the retinoscope, ophthalmoscope, and ophthalmometer.

Many varieties of figures and letters have been used for test types, but all are made on the same principle, to represent normal visual acuity at definite distances. With pupils of higher grades the ordinary test card after Snellen, and using the various letters, answers every purpose. But for the illiterate and very young it is sometimes a grave problem to use a test card with any dependence. With children cards with numbers seem to be more reliable than those with letters. Sometimes the illiterate card with the letter E pointing in various directions is satisfactory. For several years I have tried several charts with a view of obtaining one which would serve the purpose equally well for all cases. A chart composed of small words as "cat," "man," was adapted to some pupils of the primary grades. Pictures and silhouettes were unreliable. Having had occasion to refract the eyes of a deaf and dumb child, necessity lead me to design a card composed of hands with various fingers extended and in various directions. The fingers were accurately measured to conform with the type of Snellen. The success met with encouraged me to use the card on all cases, especially children. It proved the most practical of all the charts. A child not only can imitate the hands, but can be allowed to count the fingers. I have reproduced here this chart of hands, and also the chart of pictures.

The method of procedure with a test card is familiar to all. The child is placed sixteen feet from a test card, placed in proper light and at the height of the child's head. Each eye is tested separately, covering one eye which the other is being examined. In expressing the visual acuity, the distance at which the patient is stationed becomes the numerator, and the distance at which the test letters should normally be seen the denominator of the fraction.

With the present system of medical inspection of the public schools accomplishing much in the detection of cases of defective vision, and the addition of trained nurses in those sections of the city where parents are careless or because of poverty neglect the necessary attention to obtain the glasses, we are well equipped to attend to these unfortunates. Cases which for various reason would receive no attention should be referred to a competent ophthalmologist employed by the city for these examinations. Difficulty in obtaining parents to take their children to dispensaries situated at a distance from their homes makes it imperative for this work to be performed at school, after obtaining permission from the parents. If it were possible the largest school in each section should have for eye examinations a closet fitted for dark room examinations, or a portable arrangement could be used in the various schools.

Finally, children who are too poor to clean glasses, when necessary, should be supplied with them from a fund appropriated by the city. All books are supplied, and sometimes the glasses are more necessary than the book.

1300 First Street

## PSYCHOTHERAPY IN THE TREATMENT OF THE FUNCTIONAL NEUROSES.

BY ARTHUR P. HERRING, M. D.,  
Baltimore,

Associate Professor of Neuropathology; College of Physicians and Surgeons; Neurologist to St. Agnes' Hospital.

"Nervousness is a disease preeminently psychical, and a psychical disease needs psychical treatment." Mental therapeutics has been practised from the earliest ages by physicians, at times for the patients' benefit and nearly as often for their detriment. Every physician employs "unconscious therapeutics" in his daily practice, and it is only because so many reputable practitioners neglect the importance of "unconscious therapeutics" that it has not been generally used. We have been taught for so many years to deal with the physical that we look askance when anything pertaining to the psychic is mentioned. Psychotherapy is a valuable therapeutic adjunct when used intelligently and by conscientious physicians; on the other hand, it is one that readily lends itself to charlatanism and quackery in the hands of the unscrupulous doctor and the gullible patient. The success and rapid growth, especially in this country, of the various faith cures, Christian scientists, magnetic healers, etc., is due to the mental impression these people are able to make upon the American public. That they cure a great many of the functional neuroses most of us must admit, especially when we experience patients leaving us and going over to the various faddists, after we have exhausted our stock of drugs without any beneficial effect. The time has come when we must seize upon truth "where'er 'tis found, on foe or friendly ground," and use every available means to relieve the misery and suffering of the nervous patients.

It is unfortunate that the subject of psychotherapy is so frequently neglected in the medical curriculum, and I fear that students go out from our schools with the idea that anything psychic is shrouded in mysticism and often charlatanism. That suggestion often powerfully affects the progress of a case for good or for ill every experienced practitioner will admit. It is a helpful adjunct in the treatment of functional neuroses, and even in incurable cases it often aids in keeping the patient comfortable. There are, I fear, very few physicians in this country who rely entirely upon psychotherapy in treating the nervous patient. We have not the temerity of our French confrères, Dubois, Déjerine, and others, who isolate their patients and depend entirely upon suggestion or persuasion to cure them. Weir Mitchell over thirty years ago blazed the way for our methods in psychotherapy in his *Fat and Blood and How to Make Them*. This little book has probably done more to relieve the sufferings of neurotic women than any other writing on the subject. This work was taken up enthusiastically by W. S. Playfair in England, and resulted in curing a great many nervous cases. In France, Charcot and his followers made use of hypnotism in treating cases of hysteria. Liebeault and the "Nancy school" practiced suggestion in waking state. Both methods, however, have the objection of substituting the will of another person instead of reinforcing and strengthening the patient's own willpower and self-reliance.

Professor Dejerine, now in control of the Salpêtrière, dispenses with massage and electricity, employs rest in bed, overfeeding when indicated, and relies principally upon rigid isolation and persuasion. He explains the abnormal symptoms, and appeals to the patient's higher reasoning faculties. When this treatment is effective, and it very often is, it has the effect of giving the patients a healthy viewpoint of their condition and results in self-reliance and self-control which they did not have before. The recent writings of Janet, Loewenfeld, and Dubois has awakened a new interest in the subject of psychotherapy. Dubois's *The Psychic Treatment of Nervous Disorders* has had an extensive circulation in this country and served to place psychotherapy on a scientific basis. Taking the subject up as he does from a psychological standpoint he shows clearly the mental processes at work in the neurotic individual, and gives very definite directions, with illustrative cases, how to overcome and correct the mental and moral orthopædia. The literature dealing with the psychic factor in disease has been increasing in this country, as will be appreciated by glancing over the files of the current journals for the past five years.

In the practice of psychotherapy the personality of the physician probably plays a more important rôle than in any other department of medicine.

Barker remarks in his recent article on Psychotherapy and Reeducation that "the psychotherapist should be an honest man and an expert clinician. He should recognize the horrible reality of the misery of the psychoneurotic. He may be more successful in understanding and treating his patients if he has had himself, at least, some little experience with the fatigues and fears of neurasthenia, provided he has made a good recovery. He must be interested in functional disturbances and not simply in anatomical lesions, and he must understand that hysteria and psychasthenia are as much disease as are pneumonia or gonorrhœa, and often incapacitate the sufferer for a much longer period of time. He should be skilled in all the modern refinements of diagnosis, and should exhaust them in the study of his case before beginning his therapy." In addition to the foregoing the physician to treat successfully the neurotic patient must possess the attributes, patience, sympathy, and tact. It is only those who know the tortures undergone by functional nerve sufferers, the neurotic derelicts of both friends and physicians, and who appreciate their suffering, that can possibly put up with the trying nature of the patient and their multitudinous and often incurable ailments. The lack of these virtues among doctors fills the various health resorts at home and abroad with patients sent there because the physician could not stand the strain at home, and realizing his inability to help them, takes this as an easy way out. Tact is the unconscious mental touch, the *tactus eruditus*, by which one mind feels another and can convey to it, physically or psychically, skill, decision, and sympathy. Psychic tact, if I may use the term, is the *sine qua non* to success in treating the neurotic patient.

The foundation for most of the functional neuroses has been begun by a "nervous shock," and upon this has been reared a superstructure of varied emo-

tional symptoms. In order to successfully raze this neurotic temple it is essential first of all to get at the underlying cause, remove this if possible, and the subsequent treatment will be comparatively easy. It is necessary to obtain the patient's full and complete avowal, and to investigate the condition of the mental background and determine the mobility or immobility of their ideas; in doing so the three cardinal virtues, patience, sympathy, and tact, are to be used.

Sir Dyce Duckworth has said: "Confidence may be gained and is always strengthened by a close and careful attention to the minutest details of the case before us. All hesitation and appearance of uncertainty is to be strenuously avoided. A medical man who cannot keenly regard his patient eye to eye with firmness and directness is hardly likely to succeed. Dogmatism founded on sound principles is as good for patients and their friends as it is for students in the lecture room. We must be definite and we must be lucid."

After a thorough physical and mental examination of a patient the physician assures himself that the case is entirely functional; he can then institute rational psychotherapy and use as adjuncts the necessary physiological means to bring about a cure. Using either persuasion or suggestion, or both, because it is a difficult matter to separate the two, he will state plainly the facts of the case to the patient, telling him what caused the trouble and explaining how the different symptoms may be produced, the part the mind plays in originating and fostering the various fears and distressing symptoms. The fact that these symptoms can be relieved and cured with his cooperation, and how this is to be brought about, are impressed upon him repeatedly. Patients of average intelligence will listen to the explanation with considerable interest, and in the majority of cases enter into hearty cooperation with the doctor to bring about a speedy recovery. It is surprising to see (unless one has had the experience) how readily the average patient accepts the statement of the doctor and believes that they will get well, even after months of suffering. After once carefully listening to a recital of the patient's symptoms and explaining each one, it is much better at subsequent visits, when possible, not to again refer or allow the patient to refer to them. Keep the one idea always in view that the symptoms will disappear, and they will get entirely well. As Preston aptly expresses it in his book on *Hysteria and Certain Allied Conditions*: "All treatment, whether it be drug or hygienic measure, should be made impressive, should be tipped, as it were, with suggestion." When the case requires treatment other than that which is purely psychic we do not hesitate to use dietetics, electrotherapy, hydrotherapy, pharmacotherapy, or any physiological means to bring about a recovery. Psychotherapy should not tend to make us therapeutic nihilists.

Systematic treatment should be elastic and differently adapted to meet the needs of different temperaments and circumstances in patients, no two of whom are ever quite alike. What we want to secure is a central will reassured, instructed, strengthened, and set free from worrying trammels, to play its proper part as director general of the personality. To assure the cure of the sick it is not enough to

correct their logical defects; one must also teach them a philosophical conception of life, in the stoical sense, so that they can adapt it to their case.

By physical methods we may give them a physiological basis of personality, but by psychic means we teach them to educate and assimilate their conscious material and maintain a condition of adaptive stability in relation to their environment.

The ambulatory neurotic is rather difficult to handle. It is far preferable when possible to remove the patient from sympathizing friends and relatives and place them in a hospital or sanatorium. Here the patient is under close surveillance, and the many necessary details can be successfully enforced. They are free from the various annoyances associated with their home or business environment, and realize that the object in view is to get well, hence the mind is more receptive to psychotherapeutic influences and recovery is often materially hastened.

So much for the immediate care of the nervous patient. Of equal importance is the after care of the psychasthenic or neurasthenic. It is often impossible for the average patient to remain in the hospital until complete recovery ensues; with such patients it is advisable to keep in touch for a while until the last vestige of the neurosis disappears. This can be satisfactorily carried out by means of psychotherapeutic letters (Oppenheim). In addition to keeping in touch with the patient and trying as far as possible to remove all exciting influences that would tend to cause a recurrence of the malady, it has been our custom, especially with the poorer class of patients, to have the district nurse of the charity organization visit these patients in their homes, and advise them how to live and manage their affairs with the least amount of friction or worry. It is manifestly useless to place a patient in the hospital for six or eight weeks, cure them of neurasthenia, then send them back again amid the same uncongenial surroundings, and expect a continuance of the good accomplished during their stay in the hospital. See Cabot *Methods at Massachusetts General Hospital*.

I am not ignorant of the fact that a great many of our so called cures often times relapse and drift about from one physician to another, while we congratulate ourselves that we have made a successful cure.

"The nervous patient is on the path to recovery as soon as he has the conviction that he is going to be cured; he is cured on the day when he believes himself to be cured."—Dubois.

Rational psychotherapy requires time to effect a complete transformation of a mind that has been beset with doubts and fears for months. If we persist in our efforts to reeducate the neurotic sufferers we cannot at last hope for a permanent result.

A few illustrative cases have been selected from the neurological wards at St. Agnes Hospital. The histories are presented in brief abstract form, as the details would occupy considerable space, and not be specially interesting to the average reader.

CASE I.—Female, aged twenty-nine, with the following symptoms: nervousness; insomnia; cure.

Mrs. C., age twenty-nine, factory girl, was admitted to the public ward of St. Agnes Hospital on May 6, 1907, complaining of nervousness and loss of sleep.

Family history: Mother is subject to nervous attacks

Paternal aunt had "mental trouble." One brother died of consumption.

Previous history: Had smallpox ten years ago, and scarlet fever four years ago, which left her with nervous trouble. Patient had had attacks of heartburn; and felt as though pins and needles were sticking in her; she also had had "electric shocks," and could not sleep well. Patient taught a country school for several years; on account of the nervousness increasing she left the country and came to the city, where she worked in a wholesale drug house for a while, but could not continue, as she was getting worse all of the time.

Present condition: Onset of illness had been gradual. Patient was very much depressed and could not sleep. Had thought of committing suicide; had a fear of something dreadful going to happen. Memory was poor for recent events. Easily frightened without cause. Thought she was going to become insane. Would not talk about her troubles unless urged. Had been losing weight. Appetite poor, bowels constipated. Had no somatic symptoms. Physical condition showed no evidence of organic disease.

Treatment: Patient put to bed and isolated. Milk diet for the first week, and then three full meals with milk between meals. She was told that there was no physical trouble and assured of the fact that recovery was bound to come if she would only help. However, recovery was not as rapid as it should have been, and one day after a lengthy conversation the patient's "complete avowal" was obtained and a thorough explanation of each symptom given. After that the change was remarkable. The fears and distressing symptoms rapidly disappeared, and the patient left the hospital very much better.

Unfortunately, she was allowed to go back to uncongenial surroundings, and the old anxiety and fear began to return. She was put in touch with a district nurse, who obtained a position for her amid surroundings that were helpful, and when last heard from she was feeling very well. Abstract from a letter received September 2: "Yes, I am feeling very much better; in fact, I have not been so well for years. Life is really a pleasure now."

CASE II.—Psychasthenia. Simple goitre; morbid fears; fatigability; despondency; gain of twelve pounds; cure.

Mrs. B., age twenty-nine, entered private ward, St. Agnes Hospital, July 9th, complaining of nervousness and fear of walking.

Family history was negative.

Previous history: Patient had enjoyed good health until after death of her husband, whom she nursed for nearly two years almost constantly. Shortly after his death the nervous breakdown occurred. Patient was unable to eat, could not walk any distance, was always tired, became very despondent, lost weight rapidly, suffered from palpitation of the heart and accumulation of gas on the stomach.

Present condition: Patient was very weak: Seemed to have lost all hope of ever getting better, was quiet and despondent. Took very little interest in her condition or the surroundings. Said she was afraid to eat and afraid to walk.

Physical examination: Patient was emaciated, mucous membranes pale; pupils dilated and active; no exophthalmos; slight bilateral enlargement of thyroid gland; no bruit; no thrill; heart rapid, soft blowing systolic murmur at apex; lungs clear; reflexes normal. Examination of abdomen was negative except for a slight enteroptosis. Dermatographia was present. Muscle tone was fairly good. Bowels were constipated. There were no delusions or hallucinations, but a mild affect depression. She replied normally to questions, but expressed some of mistrust and emotional lability.

Treatment: Rest and isolation; milk diet for a week and then forced feeding. Persuasion. Cold baths and massage. Rapid recovery. Gain in weight and mental condition cleared up. Patient bright and self confident. The following is quoted verbatim from a letter received on September 13, 1907: "I am feeling so well that I hardly feel like the same person of two months ago. Yesterday was just one month since I left St. Agnes and in that time I have gained about seventeen pounds in weight. I am enjoying plenty of pure milk and fresh country eggs, and delightful country air, and everywhere is beautiful, and in a few words I feel like (I repeat and emphasize) like."

CASE III.—Neurasthenia; persistent vomiting; insomnia; loss of weight; depression; cure.

Mrs. L., age thirty-one. Entered private ward, St. Agnes Hospital, complaining of nervousness and stomach trouble. Family history was negative.

Previous history: Patient had been healthy until after the death of her mother, when family trouble and worry started the present nervous condition.

Present condition: For past eight months patient had been fed almost constantly by rectal tube, as she had suffered from persistent nervous vomiting. Had been very emotional and irritable, at other times moody and depressed, unable to sleep, and had resorted to hypnotics almost constantly for the past eight months. There had been rapid loss of weight. Complained of headache and numbness and tingling of different parts of the body. Easily fatigued. No desire or energy to go about.

Physical examination: A careful physical examination revealed nothing abnormal, except pale mucous membrane and some emaciation.

Treatment: Isolation; complete rest; milk diet for one week, then overfeeding. After one thorough explanation of patient's condition and forcibly impressing upon her the fact that she would improve rapidly and get entirely well, no further trouble was experienced. There was no nausea or vomiting. Patient ate heartily and gained weight rapidly. Left hospital at end of four weeks, perfectly well.

CASE IV.—Hysteroneurasthenia; "stomach trouble"; scoliosis; hysterical paraplegia; parasthesia of legs; crying spells; improvement.

Mrs. H., age forty-two, entered private ward February 4th, complaining of indigestion and general weakness.

Family history was negative.

Previous history: Patient said she "had never known a well day." Had usual diseases of childhood. When sixteen years old a lateral curvature of the spine developed. Had never been able to do any hard work. Had suffered from severe attack of gastritis three years ago; following this attack there was a paralysis of both legs for a month, without any involvement of bladder or rectum. Patient had had two other similar paraplegia attacks, which would come on slowly and disappear rapidly under psychic stimulation. When riding in an electric street car she stated that she could feel the electricity through the floor of the car. Her limbs always felt stronger after such an experience.

Present condition: Patient had been unable to digest any solid food for some weeks, and had lost weight recently. Great weakness. Easily exhausted. Complained of "internal twitching of nerves of stomach, feels like a dozen children in stomach." Had frequent attacks of vertigo, especially when sitting at the table.

Physical examination was negative except for the spinal curvature.

Treatment: Isolation; complete rest; milk diet for one week, and then overfeeding. Psychotherapy. The symptoms were explained, and the patient encouraged to believe she would get well. Baths, massage, etc., given. Improvement at first was slow. Gradually the patient was made to realize that she could get well, and just as soon as she felt in her own mind that good health was possible, she began to improve. Daily encouragement by both doctor and nurse was necessary, with the result that when the patient left the hospital she reeducated her mind to a healthy viewpoint.

330 NORTH CHARLES STREET.

## A CLINICAL STUDY OF GENERAL ANÆSTHESIA.\*

By ALEXANDER W. BLAIN, JR., M. D.,  
Detroit, Mich.,

Senior Resident Physician, Harper Hospital.

In this late day and age, when the administration of an anesthetic may truly be said to be the most common procedure in surgery, it may appear to be but repetition to add still another contribution to the already voluminous literature on the subject.

Extended observations during the past three years have, however, led me to believe that there

\*Read at meeting of Wayne County (Mich.) Medical Society, March 16, 1908.

is no subject in general medicine which is more misunderstood, and few that cause more needless deaths and suffering, owing to the misunderstandings on the part of the profession, than the technique and selection of the anæsthetic.

It is not my purpose here to call attention to the shortcomings of our profession, and I have withheld writing the following with the hope that some more mature member of our society, with years of experience and observation, would call attention to some of the fallacies under which medical men are now laboring. But as such a thesis is still forthcoming, I will attempt the same, yet not having forgotten that "fools rush in where angels fear to tread."

The advent of anæsthesia marked the beginning of modern surgery, of the marvelous achievements we need not enumerate here. The startling triumphs of the past century may not be reduplicated, but there is still room for wonderful improvements on the discoveries of the past; especially is this true in regard to clinical methods.

Modern instruments, chemical research, and a better knowledge of physiology, pathology, *et cetera*, have all aided in bettering our knowledge of disease and its treatment. But there is still a tendency to overestimate laboratory methods, which often have little bearing on practical results. Thus the Hyderabad Commission in Europe found that chloroform was safer as an anæsthetic than ether. While the investigations of the commission were exhaustive, their results bear little relation to actual results in human subjects, for anæsthesia in dogs cannot be used as a criterion of results in the human subject. I simply mention this instance in passing to show how investigations are given to and accepted by the profession as final, where in reality they are of but little clinical significance.

We have not time here for a complete résumé of general anæsthesia. Ether, chloroform, and nitrous oxide are the drugs in general use the world over to-day. Various other agents have been recommended from time to time and combinations of the above, but most of them for various reasons have been dropped by the wayside.

Of local and spinal anæsthesia we have little to say here. The latter, however, bids fair as a future method in a goodly number of cases. I fail to see any advantage over general anæsthesia as a routine procedure, though it doubtless will find a field of usefulness. Local anæsthesia has a large range of usefulness. While not coming within the scope of this paper, I may be permitted to say but one word. In infiltration anæsthesia the drug employed often plays so small a part that the patient should not be subjected to the possible toxic action of cocaine when a 0.1 per cent. solution or sterile water will often give as good results as a ten per cent. solution.

Morphine, hyoscine, and cactine compound as a general anæsthetic I mention simply to condemn. It has no place in surgery.

The comparative safety of ether and chloroform has long been a much mooted subject, not in this country alone, but in Europe. Abroad, especially in England, chloroform still holds sway. In this country ether is favored, and is rapidly gaining further

ground. During my short period I have seen the abolishment of chloroform by a large number of surgeons. But its use to-day is still too large, especially among the general practitioners and in cases where it is supposed to be indicated. It is upon this subject of indications which we wish to lay special stress.

Most textbooks on surgery devote much attention to the indications and counterindications of chloroform and ether, and it is upon this basis that so many men select chloroform to the detriment of their patient. That these classical indications are not backed by clinical experience I thoroughly believe, and that the many set indications are not well grounded we shall attempt to show.

Statistics, especially medical, are unreliable, yet there are some known facts which will bear consideration. Over 100,000 ether administrations have been given at one leading Eastern hospital without a death which could be attributed to that agent alone, while in England in one year there were no less than ninety-six published deaths from chloroform, and this probably is only a small proportion of the fatalities in that country during that period. If the fatalities from chloroform in this city during the past few years could be compiled the list would be appalling. I believe the ratio would reach more than one death in each five hundred administrations. Not a few deaths occur at Harper Hospital each year as a result of the use of this drug.

In the tropics and in the time of war, when the subject of bulk is an important issue, chloroform fills a rôle which is unexchangeable. In the Northern States, such as Michigan, its use, except in child delivery, is, in my opinion, next to criminal.

The varying results of comparative safety of these different agents in the hands of operators are different for several reasons. Thus the results of so ardent an advocate of chloroform as Sir Victor Horsley, who has his own anæsthetist—a trained specialist—are not to be compared with the work of a novice, often not even a nurse or medical student. But one thing is certain, chloroform is extremely dangerous, even in the hands of an expert. That deaths do occur from ether, I do believe, but they are in all instances unnecessary deaths. They are due to a lack of knowledge of the drug, its physiological action, and the simple technique of its administration.

There are many points aside from the mere giving of the drug which have much bearing on the patient. The relation between the anæsthetist and the patient is unique. Often the latter has perfect confidence in the surgeon, but a greater fear of the anæsthetist. It is important in every case that the anæsthetist should know his patient, and that he should inspire confidence in his part of the work as well as the surgeon. So often we see a patient wheeled from his bed to the operating room in our largest hospitals, a cone put over the face, and the first words of the anæsthetist are: "Take a deep breath."

It is impossible to enumerate here what routine is to be followed with each patient, but there are a

few points which bear consideration: 1. A conversation regarding the patient's illness; 2. An examination of the patient's heart and mouth with reference to the tongue, teeth, etc., and, third, a conversation on some subject having no bearing on the patient's trouble, the latter to be started shortly before the administration of the ether. This, of course, is not practical in every case, but in most instances will accomplish the most charming of results; thus, a farmer will talk of his crops, a sportsman of hunting, a child on things at school, *et cætera*. This advice, when carried out with a little tact, consumes no extra time and saves much time after the anæsthetic is once begun. I can't dwell upon this point too long, for it is a most neglected point, especially in our hospitals.

Another thing which is not considered is the relation between the surgeon and the anæsthetist. Usually the administration of the anæsthetic is designated to the younger members of the staff of resident physicians or to the externes. I believe that a surgeon should be commander of his anæsthetist, yet at the same time the anæsthetist should be given more consideration than he often receives by some of our local surgeons.

It is unfortunate that only a few of our surgeons have any knowledge of the proper methods of administration or of the physiological action of ether.

Thus the young anæsthetist is often scared out of his wits by one he most fears—possibly his professor at college—and often prevented from doing good work by remarks on the part of the surgeon.

Too much has been claimed for the various complicated cones; in my experience none of the patented cones have any advantage over the simple Esh-march or its modifications. As a general thing, the smaller the cone the better, as it does not cover up the face and eyes, and can be managed by one hand. It, moreover, gives a chance to regulate the dosage.

Proper etherization has been more correctly termed "ether air anæsthesia." We hear much nowadays about the drop method, but, as a matter of fact, it is not common to see it given that way. As a rule it is literally poured on. The cone should be placed on the face, and one drop of ether given, about fifteen seconds later a second drop, and so on until the patient becomes accustomed to the odor; it can be then given a little faster, but always by drops.

The drug should, of course, be fresh, and should be administered from a three or four ounce bottle, through a small hole in the cork, and never from the large cans in which it is packed, as in this way it is impossible to regulate the dosage. The ether should also be warmed to almost body temperature. This can be usually accomplished by holding the bottle in the hand for a few minutes.

From two to seven ounces may be given as the dose of ether, and it should be given with the same thought of physiological action as one would use in giving digitalis, aconite, or any other drug. Of course we expect that the patient has been properly prepared beforehand and that the man holding the knife is a surgeon. In the average operation of whatever sort it is seldom necessary to give more. Previous to operation, one eighth to one fourth grain of morphine, hypodermatically, is often of benefit and aids considerably. While not always

necessary, except in drinkers, *et cætera*, who take no anæsthetic well, it is a good routine practice. Atropine is also of much value in some cases.

The importance of the operation versus the anæsthetic as viewed by the surgeon was recently well illustrated, and I relate it here to show the minor importance placed by surgeons in methods of giving ether. The surgeon, an eminent Eastern specialist, was operating upon a patient for brain tumor. The anæsthetist was placed under a cover which extended over the patient's face, and allowed to give the ether from a Squibb's can. It is of the utmost importance to observe strict asepsis in surgery, but never to the total exclusion of a proper anæsthetic. It is needless to say that the anæsthetist under such conditions, himself saturated and working in the dark, could not do justice to the patient.

Ether given as I have outlined is not unpleasant to a large proportion of patients. Nitrous oxide as a general anæsthetic in minor operations is too familiar to all of us to dwell upon here. In major surgery it is well suited in many cases, as in prostatectomies in old men, the drainage of an appendicular abscess in much debilitated patients, etc. But its use ends here. In the average appendectomy, or any other abdominal operation, its use is not good practice, regardless of the amount of skill possessed by the anæsthetist. Nitrous oxide as an antecedent to etherization is advised by some surgeons. It has some points in its favor, but likewise its disadvantages. The apparatus necessary for gas anæsthesia is often startling to a patient, and the stage of excitement, which can be overcome in the majority of cases by ether alone, as I have suggested, is sometimes marked as the patient is coming out of the gas and going under the ether. Here the tendency again is to give too much ether. The cone should not be saturated, but the drug should be given by drops.

Turck<sup>1</sup> has shown that the phenomenon of shock can be produced in dogs by anæsthesia alone. Clinically, however, the slight shock of ether given in its physiological limit is of no significance, and in the majority of cases the drug acts only as a slight stimulant. On the other hand, the extreme depression of chloroform is often marked, even with a comparatively small dose. Extreme nausea and vomiting following anæsthesia is unnecessary in the great majority of cases. It is due usually to a toxic dose. The stomach, as is well known, is one of the main routes of excretion of the anæsthetic, ether or chloroform. When the blood is saturated with ether, the stomach is called upon to aid elimination, and nausea and vomiting are the natural consequences.

The foolishness of giving drugs for this condition can readily be seen. A glass of lukewarm water with ten grains of sodium bicarbonate or sodium chloride will wash out the stomach and carry with it the offending agent. Bismuth, charcoal, the carminatives, etc., are worse than useless.

The habit of washing the stomach by means of a tube, immediately following anæsthesia, is dangerous, and invariably harmful. A patient ordinarily should be waken up by the time the bandage is pinned

up. I have seen them sit up after a breast has been amputated so as to allow the bandage to be put on with more ease, and ask the surgeon regarding his opinion of the possible malignancy of the growth.

The patient is, or usually should be, awakened by the time it is necessary to proceed with the stomach washing. If this is insisted upon, it is necessary to give from one to three extra ounces of ether in order to relax the patient sufficiently to allow of opening the mouth. The patient has thus so much more ether to excrete, and thus nausea is far greater as a rule. There are other dangers in connection with this method which are obvious at this time.

There are few points in connection with technique which need emphasis here: First, do not use tongue forceps; they are cruel, and are not necessary in one case out of a hundred; second, do not touch the conjunctiva with your finger. It is never necessary, and sometimes it causes trouble afterwards. At the same time it is important to see that the lids are kept closed during the administration of the anæsthetic, so that the conjunctiva will not become dry; third, do not use too much force in holding the patient's jaw forward, for while it is occasionally necessary to lift the jaw up and keep it there, too much force will often cause the parts to become very painful.

The idea that the patient's head should be lowered is erroneous. As a rule the patient's head should be raised on a pillow. This is contrary to the teachings in most textbooks, but patients invariably do better by this method.

Cyanosis, excessive mucus, after nausea, and vomiting are rare with the drop method, and the fault rests with the anæsthetist, and should not be laid to the drug employed. All these conditions are the result of a too concentrated vapor or the toxic action of an overdose. Much has been said regarding the after effects of ether anæsthesia. Pneumonia, nephritis, fatty degeneration, and a multiplicity of conditions are given as the direct result of ether. As a matter of fact, these conditions are very rare; moreover, they are fully as common with chloroform as with ether. It is sometimes forgotten that these conditions occur as sequelæ of the disease from which the patient is suffering, and thus often the blame is laid to the anæsthetic, where it probably bears no relation, except that, together with the operation, it aided in lowering the patient's vitality, and thus increased his susceptibility.

That the extremes of age bear ether well is borne out by a large series of cases. Here again chloroform is so often selected owing to the bugbear, "ether pneumonia," which still lingers in the minds of physicians, or "a few drops is all that is necessary" for the tonsilotomy or circumcision, with the unfortunate result that a perfectly healthy individual dies a martyr, together with others, which will finally change the physician's point of view.

#### Conclusions.

The following practical deductions may be drawn from the present studies:

1. Chloroform is a dangerous drug, and should be totally eliminated from the armamentarium of the surgeon.

<sup>1</sup>Trans. Am. Med. Assoc., Nov. 2, 1905.

2. The so called "morphine-hyoscine anæsthesia" is unscientific, and is equally as dangerous as chloroform alone. It has no place in surgery.

3. The comparative safety of ether and chloroform cannot be based on our present statistics, but one point is certain: chloroform is always dangerous, while ether given with a comparative amount of skill, is absolutely safe.

4. Nitrous oxide as a general anæsthetic is occasionally of value, but its use is extremely limited, as good results can be obtained in these cases where gas is used by ether, if the latter is given with the same amount of skill as is necessary in giving the gas.

5. The anæsthetist should pay more attention to his patient, and the surgeon give more consideration to the duties of the anæsthetist.

6. The indications in a surgical operation are for ether, and the counterindications are nil.

In conclusion I want to express my thanks to Dr. W. A. Fenner, Dr. F. E. Bowman, and other members of the resident staff for records, observations, etc., which have been material for deductions on no small proportion of the past five thousand surgical cases treated at Harper Hospital.

#### A CASE OF ABSCESS OF THE FRONTAL LOBE OF TRAUMATIC ORIGIN.\*

BY FIELDING LEWIS TAYLOR, M. A., M. D.,  
New York.

Thomas H., aged twenty-seven years, was struck with a brick above the right eye in a street fight in May, 1906, about four months before I saw him. September 13th. He was not rendered unconscious by the blow. The resulting wound was sutured in a hospital in a New England city, and he returned to his work as a railroad section hand the following day.

After a month considerable inflammation about the wound, which had healed, caused him to return to the hospital, where a superficial abscess was opened and several small pieces of brick and some spicula of bone were removed by the attending surgeon. Although the wound healed, the patient suffered from intense headache at times, which was most marked over the occiput; he could scarcely stand up, while he could move his legs fully though feebly in bed. He was obstinately constipated and vomited very frequently. His intellect was sluggish, and he could not sleep. His friends became dissatisfied and removed him to his home in the country. Here he remained most of the time in bed, suffering tortures with headache and vomiting, until September 12, 1906, when he was seen by Dr. A. B. Tucker, who brought him to a sanatorium in this city. I saw him the afternoon of the same day with Dr. Tucker.

The patient was terribly emaciated. He yawned every few minutes. If his attention was attracted he would answer questions sluggishly but intelligently. Otherwise he was apathetic. His pupils were moderately dilated and responded in a measure to light and distance. Vision was decidedly diminished. Dr. Claiborne examined the eyes and found bilateral optic neuritis more advanced on the left side. There was slight paresis of the left side of the face without ptosis. The tongue could be put partially protruded, and deviated slightly to the left. There was distinct weakness of grip in the left hand.

He could move his legs. The abdominal and rectal examinations were well marked. The Babinski sign was not present. The knee-jerk sign was marked on both sides. The reflexes of the neck and back were very brisk. He complained of acute pain in the occiput and down the spine.

There was incontinence of urine and feces and peristalsis.

\*Read before the Section on Surgery of the New York Academy of Medicine, January, 1908.

ent vomiting. The pulse was 72, respiration 16, and rectal temperature 98° F. The leucocyte count was 8,000, of which seventy-nine per cent. were polymorphonuclear neutrophils, nineteen per cent. lymphocytes, one per cent. eosinophiles, and one per cent. basophiles.

There was an irregular cicatrix crossing the right temporal ridge about one inch above the external angular process of the orbit and adherent to the bone, in which a fissure could be felt. The skin in the neighborhood was oedematous, and slight fluctuation and congestion were present at the inner end of the scar. There was oedema of the right upper eyelid. The whole anterior part of the head on the right was tender on deep pressure. There was a difference in the percussion note on the two sides, but this I thought might be attributable to the oedema.

The patient's pulse fell to 53 during the night. He was operated upon the next day. An incision was made in the line of the old cicatrix. There was a drop of pus at its inner end. The fissure was enlarged with a bone forceps, and a round opening about an inch in diameter made with its centre about an inch above the junction of the middle and outer thirds of the supraorbital ridge. The dura bulged into the wound and was incised. There was some inspissated pus inside, which was removed. The anterior tip of the frontal lobe presented. It was very hard and did not pulsate. A very large hypodermic needle was pushed upward, backward, and inward, and encountered pus at the depth of half an inch. Upwards of two ounces of pus were evacuated with an artery clamp. The cavity was simply drained with a piece of rubber tubing and weak iodoform gauze without being scraped or irrigated. A hernia cerebri developed a few days later, about half the size of a hen's egg, which sloughed off, after which the wound closed.

The patient recovered his intelligence at once, except for the fact that for three days occasionally he would spring suddenly over to the right edge of the bed to catch hold of a table or other object, under the impression that the bed was falling over to the left; and that for more than a week he could not be convinced that he was not ill at his home in the country. The day after the operation his slight hemiparesis disappeared, his patellar reflexes returned, he retained his urine and feces, and stopped vomiting. He passed enormous quantities of urine of low specific gravity without albumin or sugar, and soon developed a ravenous appetite. The pain and stiffness in the neck and upper part of the spine caused him more trouble than anything else, but gradually disappeared.

He returned home October 17th, apparently well, except that he was nearly blind in his left eye and could see but poorly with his right. I last saw him on December 3, 1906. He stated that ten days after his discharge he had some pain in the neighborhood of the wound during the day; the same night he awoke with considerable pain in the occiput and down the spine, and vomited. The pain in the occiput lasted three days and ended with an attack of vertigo. When I saw him his leucocyte count was 6,000; his pulse was 72, full, soft, and regular. His patellar reflexes were normal, the wrist and elbow reflexes seemed slightly exaggerated; the strength of the hands was normal; he said that his legs seemed somewhat weak at times. There was no stiffness of the neck and spine, and no tenderness about the wound. The right eye was worse, he could only distinguish light. The left he thought somewhat improved, as he could count figures across a poorly lighted room.

He again returned to his home in a comparatively inaccessible place, about 100 miles from New York. I heard from him several times during last year that he was well, except that his eyesight was not improving. He made arrangements to come to New York to be treated for his eyes on November 1, 1907, and was in excellent spirits when I heard from him the latter part of September. I was then appointed to learn from his employer on October 30th that he had died on October 23d. On Thursday, October 17th, he complained of severe headache, which continued Friday and Saturday. During the day Saturday he had two convulsions, from which he recovered; during Saturday night he had four after which he could be aroused only with difficulty. Sunday he had a fit every ten minutes, and this continued until his death, on Monday afternoon.

I regret that I was not sent for. As I think that he had developed a secondary abscess by the extension of infection from the frontal lobe, I have been taxed, I could at least have

done an autopsy.) That such was the case is not the only explanation for the convulsions, as the scar resulting from the abscess and subsequent hernia cerebri was very large.

I postponed reporting this case for a year, awaiting the development of sequelæ. That a secondary abscess does develop in the neighborhood or even at some distance from the first, and that, too, after a considerable lapse of time, is amply proved by a review of the literature of the subject, with which I shall not burden you. This is a grave danger in cases that have been operated on with apparent success.

On the other hand, to show that a scar following an abscess may give rise to epileptic convulsions leading to status epilepticus and death, I shall cite only the following case: In the *Cincinnati Lancet Clinic* for 1906 (New series, lvi, p. 401), Dr. J. C. Oliver reports the further history of a case of abscess of the frontal lobe, which was operated on on September 11, 1895, and reported as cured in the *Journal of the American Medical Association*, of May 30, 1896. Eleven months after the operation the patient, a man twenty-one years of age, developed epilepsy, and had about one paroxysm a month for five years. The interval between the paroxysms gradually lengthened, until on February 19, 1904, he had several convulsions in rapid succession. A few days later he developed status epilepticus, and died of exhaustion. The only lesion found on autopsy was the cicatrix of the abscess, which extended into and involved the motor area.

173 WEST SEVENTY-THIRD STREET.

## THE PREVALENCE OF INFECTIONS IN CHILDHOOD.\*

BY MAURICE OSTHEIMER, M. D.,  
Philadelphia,

Instructor in Pædiatrics, University of Pennsylvania.

The time is not very far off when you are likely to be called to see sick children, and it may be difficult, in many cases, to make a diagnosis. You may see an infant who continues to cry, and this constant crying is the dominant symptom, with some fretfulness possibly, and perhaps some fever and loss of appetite; examination shows nothing beyond a reddened throat and slightly coated tongue, and before you have exactly made up your mind what the trouble is, the mother or nurse has discovered a running ear! Here you had an infection which became localized in the middle ear. Other children may escape otitis media, yet develop coryza, laryngitis, amygdalitis, adenitis, parotitis, bronchitis, pneumonia, or pleurisy as the result of the same or similar infectious microorganisms.

Then you may see a larger child, coming with the history of having had sore throat and fever, without other disturbance. Some weeks later the attack of amygdalitis seems to be repeated, this time with signs of decided weakness, and your examination shows slight irregularity in the heart's action. It is then only a question of the number of recurrent attacks, either with throat or joint symptoms, until you discover the murmur of endocarditis, perhaps with signs of myocarditis or even pericarditis. And

probing into the antecedent history of some of these children, you will find that there had been, years before, an attack of scarlet fever. And in the older children, those approaching puberty, the previous occurrence of articular rheumatism or chorea may be revealed, and your questions will bring to light the history of numerous, repeated attacks of infection.

You should all know how very easily and rapidly gastritis, gastroenteritis, or enteritis develops in a young child. Generally the food, the heat, or exposure to sudden change in temperature is blamed; but you will remember that there are always infectious microbes present. Just which one plays the rôle of predisposing cause and which that of exciting cause is still in doubt, but microorganisms in great quantity and variety are found on examination.

So far I have spoken of infection in general; but you have already learned that one sort of coccus has been considered the specific agent in epidemic meningitis, another in pneumonia, another in gonorrhœa, and probably several groups, distinctive morphologically, in erysipelas, scarlet fever, and rheumatism. Bacilli appear to be the cause of tuberculosis, typhoid fever, influenza, dysentery, and diphtheria; while protozoa are supposed to be the infecting agents in malaria, relapsing fever, small-pox, and syphilis.

Your surgical experience has made you familiar with the various wound and skin infections, pyæmia, and septicæmia, as well as the different forms of genitourinary infections. And you have studied how the blood and lymphatic streams spread the disease germs.

Yet our knowledge of disease is still so incomplete that, while we consider many diseases as infectious in character, the infecting agents have not so far been surely distinguished. Here we should group scarlet fever, rheumatism, poliomyelitis, whooping cough, measles, and chickenpox.

If we go over the diseases already mentioned, we find remaining very few of the illnesses of childhood. Of course you will say "What of rickets and infantile scurvy?" Well, who can tell how soon they, too, may be classed among the infections!

Realizing, then, the very great rôle played by infections in children, it is your place, as physicians, to prevent their occurrence among your young patients. Therefore a general prophylactic treatment, for the prevention of infections, is of decided value to keep the children well.

As most of the infections are believed to enter the body through the lymphatic tissues of the nasopharynx, the most important thing you can do is to keep the nose and mouth clean. This should be begun in infancy, and kept up regularly and continuously until later life. Nurses and mothers must learn to clean noses, mouths, and throats early and with regularity; and signs of the presence of any abnormality, such as adenoids, should necessitate an immediate visit to the specialist.

Here I want to remind you once again, as I have so often before, that all cases of cervical adenitis are not tuberculous, the majority of such swellings in children being the direct result of other infections.

See to it that all infants under your charge are

\*Address given before the June Twinn Medical Society, University of Pennsylvania, March 2, 1907.

vaccinated between six weeks and three months of age; and order that all children be kept in the open air as much as possible during infancy and childhood. Besides, care must be taken in the preparation of all food for children, to prevent infecting the gastrointestinal tract.

If any child should come in contact with an infectious disease, precautions should be taken at once, such as the injection of an immunizing dose of antitoxine in case of diphtheria. And the possibility of treating all infections by the opsonic method seems to offer better results than any one method thus far advanced.

In closing, I beg of you to remember the great prevalence of infections in childhood, and hope that your good care will prevent many cases of infection in the future.

225 SOUTH TWENTIETH STREET.

#### SOME RANDOM NOTES ON LEPROSY IN THE FAR EAST.

By CHARLES S. BRADDOCK, JR., Ph. G., M. D.,  
Haddonfield, N. J.,

Late Chief Medical Inspector Royal Siamese Government.

Leprosy is a disease which is looked upon with horror by the people of the Occident. In the Orient, however, through long association, it is looked upon far differently and with more tolerance.

From personal observation my opinion is that leprosy is not nearly as contagious as is usually considered by the average man. In the Far East, and I speak more particularly of Siam and the Malay peninsula, lepers mingle with the rest of the people, travel in the same public conveyances, sit on the corners of the streets near public bridges and meeting places, and solicit alms in the midst of the great population, and the disease, while prevalent, does not seem to increase materially.

There is no segregation by the government of the lepers, and they are free to come and go at their own free will.

I notice, however, that the children of the lepers also develop leprosy, and that seems to be the mode of propagation of the disease. I never was able to get a single history of any one having acquired the disease directly from another, but had many children brought to me showing the first signs of the disease, usually manifested by a white patch slowly spreading over some part of the body, most usually the face, wrist, or ankle and usually anæsthetic, but not always. In every case on inquiry I found there was a history of leprosy in the family or collateral relatives.

I believe that any one who wore the clothes of a leper would acquire the disease, but it requires personal contact. Many persons associated with the lepers for long periods without contracting the disease.

I well remember a tramcar conductor in Bangkok who was a pronounced leper, and would probably be collecting fares from the public yet if the Europeans had not protested and had him removed from his position.

The amount of alms given along the streets to the lepers is enormous, and this money is passed on

from hand to hand. I always washed my hands with an antiseptic after handling money.

At one time a row of buildings in Bangkok collapsed, killing and injuring a large number of people. One man helping to remove the injured was covered with blood from a man who was crushed. On bringing him into the street he was horrified to see the man was a leper in the last stages of leprosy. I made him change and destroy his clothing at once and bathe with an antiseptic, and he was never affected in any way. Not a pleasant predicament, however.

I have attended many patients sick with other diseases, and have only found out after a physical examination that they were lepers; also dressed their sores, and have tried various medical means for their relief, but outside of the general improvement in health and surgical cleanliness have never seen any result from medical treatment.

These cases are usually neglected ones, so that when the leprosy sores are cleaned and treated antiseptically, and the patients given strong tonics, their general health improves. I think that the best results will be obtained in the future along the lines of curative sera and antitoxines.

On a journey to the island of Puket, in the Indian Ocean, lying between the west coast of the Malay peninsula and to the south of the Mergui archipelago, my attention was called by Prince Damrong, minister of the interior of Siam, to a body of people who had called to pay their respects to him, and whom he called sea gypsies. These people had a dialect of their own, and lived in boats, roaming about the islands, and were engaged in procuring pearl shell and fishing for a living. The prince called my attention to the fact that these people, almost to a man, suffered from a skin disease, a form of ichthyosis, as the skin looked like the scales of a fish. It is a question whether it is a skin disease purely or a form of leprosy. I never saw it except in these people. It is unknown among the dwellers on the mainland. From what I could learn this disease was always known among these people, who are clannish, and do not intermarry among the Siamese or Malays.

A few months later, while traveling on another expedition in the north of Siam, near the Indo-Chinese frontier, my attention was called by the authorities to a leper village of about one hundred inhabitants. These people, all closely related by blood, had by gradual selection and other causes settled in a village together, where they lived and tilled the soil. The village was some distance from our camping place, but when getting ready to go and visit it I was informed by an orderly that they were waiting outside the camp. On going a few hundred yards away I found about thirty-five men, women, and children all squatting on the ground and all showing, in a more or less degree, a curious thickening of the tissues of the face, far more marked in some than in others; only three or four had lost fingers or toes, but all had this face disfigurement, some to so great a degree that the poor creatures looked like persons with an enormous distorted false face. It was a sad and gruesome sight. I had seen a few cases of this form of leprosy before, but never so many at one

time. A large quantity of tonic medicine was given them, for which they were very grateful. Leprous sores were almost altogether absent in these cases.

The Siamese government are contemplating building a leper colony and hospital on an island in the gulf of Siam, but it will be difficult to put isolation into operation, owing to the fact that the people have very little fear of the disease, and therefore do not want harsh measures used in separating families and isolating patients.

In conclusion I would say that I think a mistake is made in the hospital treatment in this part of the world. In treating some of the contagious diseases, such as leprosy, plague, smallpox, scarlet fever, etc., as I think none of these cases should be treated inside the four walls of a house. In the summer they should be treated in a pavilion open to the four winds of heaven, with a roof to keep off the rain and sun, and in the winter in tents to hold not over two patients, and on the removal by death of the patients the torch should be applied to the pavilion or tent, and to everything contained therein, after the removal of the body. This applies more particularly to plague. No plague case should ever be put within the four walls of a house.

### Our Readers' Discussions.

#### A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at frequent intervals. So far they have been decided upon, the further questions are as follows:

LXXIII. How do you treat seasickness? (Closed April 15, 1908.)

LXXIV. How do you treat sunstroke? (Answers due not later than May 15, 1908.)

LXXV. How do you treat cholera infantum? (Answers due not later than June 15, 1908.)

Whoever answers one of these questions in the manner most satisfactory to the editors and their advisors will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

All persons will be entitled to compete for the prize, whether subscribers or not. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish. All papers contributed become the property of the JOURNAL.

The prize of \$25 for the best essay submitted in answer to question LXXII has been awarded to Dr. J. Russell Verbruyne, of New York, whose article appeared on page 788.

#### PRIZE QUESTION NO. LXXII.

##### THE TREATMENT OF FRACTURE OF THE PATELLA.

(Concluded from page 836.)

Dr. L. W. Bagg, of Newark, N. J., remarks:

In order to decide upon the best treatment of fracture of the patella, a few important facts must be kept constantly in mind, viz., (1) the patella is a sesamoid bone, located in one of the most powerful and useful muscular mechanisms of the body; (2) its location is immediate to one of the most

dreaded fields for surgical interference; and (3) the reflections of the aponeurosis are essential to the strength and the functions of the knee joint; injury to these reflections are almost always associated with complete fracture of the patella. Bearing in mind these three points in treating such fracture, we should make a careful estimate of the degree of injury, age, occupation, and resisting power of the individual, and proper regard for the means at hand, in carrying out operative treatment, if this course is indicated. The acute attention to detail in carrying out whatever line of treatment is selected, and a painstaking attitude towards patient and injured part, until the final result is attained, are essential.

Fractures of the patella may be divided into new, transverse, comminuted, oblique, longitudinal, old or refractures—that is, those generally occurring in the line of union of previous fractures. Fractures occurring in patellæ, previously fractured, but in a fresh location, are considered as new fractures.

*Complete, Incomplete, Simple, Compound Fractures.*—Important associated conditions which may accompany these fractures are: (1) Severe abrasions of the skin and injury to adjacent tissues of such a degree as to prevent primary union; (2) wide separation of fragments; (3) tilting of fragments; (4) tears or rents of lateral portions of the aponeurosis, or lateral expansion of the quadriceps tendon, with separation; (5) folding in of the periosteum over the fragments, thus preventing good approximation; and (6) exudate and hemorrhage into the knee joint.

In view of what I have stated, let us classify our cases according to those which should be subjected to operative treatment, and those which should be treated by a retentive method.

In elderly patients operation should not be considered unless in cases of refracture, where the limb is practically useless to the individual. Patients of low power of resistance, due either to inheritance or constitutional disease, should not be subjected to operation. In comminuted fractures, when fragments are in good apposition, in oblique and longitudinal fractures, where there is no separation, do not operate.

Where fractures are complicated by injury to the skin of such a degree as to prevent primary union, wait until the skin has regained itself before operating. In cases of transverse fracture, with separation, operate. In compound fractures, with infection of the knee joint, this should be treated as any septic wound.

Three steps in treatment should be our guide: (1) To reduce the swelling and hasten absorption of the exudate and free blood; (2) to bring the fragments into apposition, and maintain their approximation until union occurs; (3) to maintain, as far as possible, the tone of quadriceps muscle, and restore the function of the knee joint.

To reduce the swelling and to alleviate pain, apply a rubber elastic bandage, from just below the knee, upward to about eight inches above the joint. This should be applied snugly, but not so as to impair the circulation of the limb or increase the pain; then apply a well padded posterior splint, slightly wider than the limb, padding well the heel. The splint

should be held in place by three pieces of zinc oxide, adhesive, about two inches in width, placed one at the ankle, one at the upper end of splint, one just below knee; then apply a flannel roller bandage from toes to groin; each bandage about three inches in width, applied snugly and evenly. Elevate the foot on pillows, about six inches, and apply ice constantly to the knee. This dressing should be taken down at the end of forty-eight hours; reapply flannel bandage, using ice until swelling is reduced. If the patient is seen immediately following injury, instead of an elastic bandage, apply a flannel bandage, kept wet, with an official solution of lead and opium, and also apply ice. This will give the patient much relief from pain, and also tend to prevent swelling, and check spasm of muscles. After six to ten days the patient will have recovered from shock, due to the injury, the injured tissues have regained themselves, and the healing process has started. This is the best time for operative treatment, provided the strictest aseptic methods can be obtained, as well as proper surgical technique, never forgetting the thought which Lister advanced, when he wrote "no man is justified in performing this operation unless he could say with a clear conscience that he considers himself morally certain to avoid the entrance of any septic mischief into the wound."

Now, what do we accomplish by operation? (1) By removing exudate and blood clots we help to avoid troublesome adhesions. (2) We restore parts to their proper anatomical relations. (3) Tilting of the fragments is immediately overcome. (4) The rents in the aponeurosis are brought into proper apposition and sutured, thus enabling us to begin early our treatment of the quadriceps muscle and knee joint, in preventing atrophy and retaining tone of muscle and restoring function of the knee joint. The patient is started on a more rapid road to recovery, thus avoiding the uncertainty and frequent complications which result from adhesions of torn and misplaced tissues.

*Operation, Incision.*—Circumlinear incisions with convexity upward seem to give the best view of the field, especially when there is a wide separation of the fragments. The deep fascia is incised, or, if already torn, its edges are retracted.

*Cleansing.*—Irrigate the knee joint and tissues thoroughly with normal salt solution, temperature 110° F., using it freely, so as to thoroughly cleanse parts. I have taken it for granted that rubber gloves should be worn. The interior of the knee joint should be let alone as far as possible from any manipulation, either with the hand or gauze sponges. The hot saline has a stimulating effect upon the injured tissues. The edges of the periosteum and tags of torn tissue are trimmed and retracted.

*Suturing.*—The fragments are held firmly and two small holes drilled from above downward, about half an inch back from fractured edge, coming out equal distance from articular surface. These holes should be equal distance as well from the centre line. When sutures are introduced and drawn taut, the fragments should then be in perfect apposition. The heavy chromicized catgut has given excellent service. The periosteum and aponeurosis, which are one layer over the patella, are brought into apposition and sutured with fine chromicized gut. It

is very important to suture the lateral portion of the torn aponeurosis. This separation is the main cause of the separation of the fragments; its proper union is necessary to attain results. A silkworm strand is passed into the joint, and another strand down to the joint, placed at each angle of the wound. The skin is now sutured either with fine catgut or silk. Dry sterile dressing is applied, and flannel bandage from the toes to the groin. Elevating the foot six inches is essential. After forty-eight hours remove dressing, and if there is no elevation of temperature or other signs of suppuration present, the silkworm strands are removed and sterile dressing reapplied as before. If sepsis is present, it will find free exit along the strands of the silkworm, thus aiding our prevention of a more general infection of the synovial membrane. At the end of fourteen days passive lateral motion of the patella should be begun, and continued daily, as well as massage of the muscles of the leg and thigh toward the knee joint for fifteen minutes twice daily. At the end of five weeks begin passive motion of the knee joint; allow patient to move around with crutches, removing splint at night; at the end of eight weeks remove all support to the knee, cautioning the patient against any muscular exertion or direct violence.

*Nonoperative Treatment.*—Treat the early stage as indicated; where absorption is tardy it is a good plan to aspirate joint. A small amount perhaps can only be removed, due to clogging of the needle, but even this will aid greatly the absorption and tend to check the development of troublesome adhesions. As soon as the swelling has been sufficiently reduced, which is toward the end of the first week, the posterior splint is applied, as before indicated; the limb is then elevated so as to relax the quadriceps extensor muscle, the upper fragment is drawn down and held by strip zinc oxide adhesive plaster in a loop, passed downward diagonally, and fastened to posterior surface of splint. A second piece is likewise adjusted to lower fragment, drawing it upward. A third strip should be placed directly over the line of fracture, drawn downward, and fastened beneath splint. This aids greatly in preventing tilting. Three or four additional strips should reinforce the strips first applied of the same width, and so placed as to cover the preceding one by two thirds of the width of the latter. The flannel bandage is then applied, and elevation is maintained.

The adhesive strips should be left on for six weeks; the muscles of the limb should be massaged toward the knee for fifteen minutes twice daily. At the end of six weeks remove splint and adhesives, and apply to the limb from the ankle to the gluteal fold a light posterior cast. This splint can be easily removed and massaged, and passive and active motion of the knee joint easily obtained. From the sixth to the eighth week, the patient is allowed up and about, with the use of crutches, being very careful to protect limb from any muscular exertion or direct violence; a simple rubber bandage should be worn for six months. Daily massage and passive motion should be continued for some months.

*Old or Recurrent Fracture.*—The upper fragment is often found adherent and many other troublesome adhesions present. If the fragments can be

brought into apposition, they should be sutured as a primary fracture, having first freshened the fractured surfaces. If the fragments cannot be brought into apposition, then the fragments are removed, and a portion of the quadriceps tendon is brought down and sutured to the patella tendon.

*Incomplete Fractures.*—In these we have no separation of fragments or tears in the aponeurosis to deal with; these should be treated as complete fractures without separation.

*Comminuted Fractures.*—Where there is no displacement of fragments the aponeurosis is probably intact. The retentive method gives us good results in these cases. Cases in which there is a separation of fragments are best treated by operation.

*Dr. S. W. Wynne, of New York, observes:*

The treatment of fracture of the patella is general and local. The former, although important, as it is in all surgical conditions, need not be dwelt upon here, as it differs in nowise from that indicated in any kind of fractures.

The local treatment is conservative or nonoperative, and radical or operative. Our first duty should be to conscientiously determine which course to follow, and in so deciding the following conditions are to be considered:

1. The availability of an experienced surgeon, skilled assistants, and an operating room where absolute antiseptic and aseptic precaution can be observed. Without these adjuncts operation is never justifiable. The dangers of opening the knee are too familiar to all to require mention; suffice to say from a standpoint of mortality alone they are relatively greater than those attending laparotomy.

2. The patient himself, who should be healthy and of a suitable age. A thorough general examination, including heart, lungs, urine, etc., is therefore in order.

3. The local condition, when the separation is three quarters of an inch or more, when the fragments are comminuted, as in those fractures caused by direct violence, when there is much effusion or hæmorrhage into the joint, when the anterior fibro-periosteal layer, blood clots, or bony spicules are interposed between the fragments, operation is indicated, provided the first two conditions can be conscientiously disposed of.

It is to be borne in mind that the nonoperative method practically in nowise endangers the life of the patient, neither does it exclude the possibility of a successful operation at a later date, and, lastly, that a good functional leg usually results and often more rapidly than when many of the operative procedures are resorted to. However, in the case of young adults in robust health, the operative treatment is to be preferred in all cases, provided, of course, the facilities for its successful performance are at hand. However, the facts in each individual case should be carefully weighed before determining upon the advice to be offered.

Should one be called to attend the patient upon the scene of the accident, further separation of the fragments and tearing of the capsule and patellar tendons, while he is being moved, is to be prevented by placing the injured leg upon an improvised posterior splint, having first bound the knee in a snug

figure 8 bandage to support the tissue, and thus control the amount of effusion, for when the capsule becomes overdilated by effusion it loses its elasticity, and absorption is slow.

The patient having been put to bed and the leg bared, a more careful examination may be made, and the line of treatment determined upon, or we may proceed with the nonoperative, while more carefully considering the advisability of an operation. Let us therefore first take up the nonoperative treatment.

It is evident that in order to secure and maintain apposition of the fragments, the effusion must first be reduced, and to that end we must bend our first efforts. Apply a snug figure 8 bandage about the knee over a moderately thick layer of cotton, place the leg upon a long posterior splint extending from the ankle to the upper one third of the thigh. Agnew's splint is admirable for the purpose. The splint is held in place by a bandage above and below the knee. A pillow may be placed beneath the heel to secure hyper extension. For the first day or two apply Leiter ice coil or ice bags. Later intermittent heat may be of benefit.

The bandage is removed and reapplied, when it becomes loosened or inspection of the part is desired.

If there is much effusion or hæmorrhage into the joint, aspiration under the most rigid observance of asepsis may be employed (blood in the knee will not clot for several days). After this procedure again support the tissues to lessen further effusion.

When the effusion has receded sufficiently to allow of the fragments being brought into fair apposition discard the first dressing, and with the leg still upon the splint draw the fragments together. The absence of crepitus denotes the presence of an interposing body; gentle manipulation will often serve to displace it. Carry a strip of adhesive plaster an inch wide and several feet long over the upper border of the upper fragment, pull the bone well down, and fasten the ends of the plaster to posterior surface of the splint below the lower level of the joint, reinforce this with another strip; now carry a third strip under the lower border of the lower fragment, draw the bone up, and fasten the plaster securely to the posterior surface of the splint above the uppermost level of the knee; then to correct the tilting of the fragments carry a strip of plaster transversely over the line of fracture, and fasten to splint.

A bandage then holds the splint in place, and is carried around the knee in figure 8 fashion. The heel may be raised upon a pillow to extend the leg and semiflex the thigh.

Each day the bandage is removed, parts are inspected, straps tightened, and bandage reapplied. As the more acute symptoms subside gentle massage may be employed daily.

At the end of the second or third week remove the splint, and with the leg in extension apply a plaster cast from the ankle to the middle of the thigh, and get the patient around on crutches. Before placing the leg in the cast the fragments may be secured by three strips of adhesive plaster. This cast is worn until the eighth week; it is then replaced by a lighter and shorter one, to be worn four to six weeks longer; canes now replace the crutches. For the first year after removal of cast, a leather

lacing knee cap is worn during the day for protection, and daily massage employed in conjunction with gentle active and passive movements.

Although this prolonged immobilization renders the joint more or less stiff, an almost certain occurrence, still the end result is better than the flail-like joint, due to the wide separation of the fragments that invariably follows early use of the joint. When practicable it is well to cut down the cast so as to permit of its daily removal for massage.

In alcoholic cases it is a wise precaution to immediately put the leg up in a cast until all danger of delirium tremens is past; thus further injury of the parts are guarded against.

Operation having been determined upon, the open method alone should be considered, as it permits of a thorough inspection of the parts, the removal of blood clots, bony splinters, and of interposing tissue, the repair of the capsule and patellar ligaments, and such other damages of the joint structures as may be present, and the perfect apposition of the fragments. The closed methods defeat the very ends for which an operation is performed.

The ligamentum patellæ, with its lateral expansions, is in reality the continuation of the tendon of the quadriceps, the patella being but a sesamoid bone that has developed in its course. The poor blood supply possessed by such bones accounts for their comparative tardiness in uniting. The necessity of repairing what is really the tendon of the quadriceps is readily apparent. And, then, why use unabsorbable suture material, as silver wire? They possess no advantage over the absorbable ones, and the objections to their use are many. Our purpose, as in all fractures, is simply to restore the parts to their normal relationship, and to thus maintain them until Nature can effect her own union, and when she has it is time for us to vacate. For Nature, too, resents permanent receiverships, and her resentment is shown in sepsis, anchylosis, etc. Properly prepared gut and kangaroo tendon fulfill every requirement.

The joint is opened by a U shaped incision, convexity preferably upward. Blood clots, bony splinters, etc. removed, the joint is flushed out with sterile normal salt solution, the part brought into normal relation, the torn edges trimmed up when necessary, or freshened up in late operations, and the tears of the capsule and lateral expansion of patella ligament and the anterior fibroperiosteal layer sutured, and to insure perfect and firm apposition of the bony fragments, especially when comminuted, a purse string suture is thrown around the circumference of the patella, drawn taut, and tied. The objection that this suture interferes with the blood supply is, I think, theoretical rather than practical. Any other injuries of the joint structures are, of course, repaired, special attention being paid perhaps to the ligamentum mucosum and the ligamenta alaria, injuries of which Dr. Flint has demonstrated so often give rise to the so called "foreign bodies" of the knee.

In closing the wound a small strip of rubber tissue is left in the joint, protruding from one of the angles of the incision, to provide for drainage of the serum that will accumulate within the first and second days. It is removed as soon as deemed advisable, usually at the end of the second or third day.

The wound is dressed in the usual fashion, and the leg placed on a posterior splint.

Passive motion is begun about the third week, and the patient allowed around on crutches.

To sum up, the treatment of fracture of the patella is operative and nonoperative. The latter seldom results in bony union—in fact, fibrous union under one half inch is considered a good result. It is to be advised, however, when the conditions for operation are unfavorable. The operative treatment should always be by the open method, and in properly selected cases good bony union should result.

*Dr. George A. Hopp, of Philadelphia, writes:*

In the treatment of fracture of the patella there are several measures which are of value. One of the most important is the functional result, also the short period of recovery, which is of greatest importance to the patient.

Fracture of the patella is a very common accident. Eighty per cent. of all the fractures are the result of direct violence; fractures which were supposed to be due to muscular contraction are comparatively rare and can only occur when the knee is extended.

There are two methods of treating fractures of the patella, the operative and nonoperative. The open operative method is the best of the operative methods, as it gives better functional results.

The operation is performed on the third or fourth day after the accident, when the patient has been more or less reconciled to bed and the swelling of the joint has ceased to increase. A semicircular flap is raised from over the fragments and all the clots are carefully turned out. Each fragment is then drilled, and they are brought in exact apposition with kangaroo tendon, which is a reliable suture and is absorbable. The objections to silver wire for suture, which many surgeons use, are that it is non-absorbable and acts as a foreign body which the patella tries to expel; as the result of this it causes the failure of bony union and movable joint.

If an x ray is taken one can see that the wire suture has been broken when passive motion was made, and this causes a second operation. After the fragments are brought together the torn fascia on the cutaneous surface of the patella is then united with sterile catgut, and one or two catgut sutures are used to join together the aponeurosis on either side if it has been extensively lacerated.

At the angle of the cutaneous incision there is left a little opening in case there should be any oozing, as no drain is inserted.

No antiseptic solution should be allowed to touch the interior of the joint. There is no occasion to wash it out, as the blood clot can be removed with ease by means of sterilized gauze.

The wound is dressed with deep and superficial dressings, with posterior splint, which immobilizes the leg. The knee is firmly bandaged and the patient put to bed. On the fifth or sixth day the bandages and the superficial dressings are removed, and the part is examined. The patient is encouraged to flex and to extend the limb, the dressings are replaced, and each day passive motion is made more and more. By the end of a few days it can be bent to right angle.

Massage is begun as soon as the wound is healed.

The patient is allowed to get up before the end of the third week, and by the end of the fourth week he is able to walk.

If this method of treatment is carried out under proper precautions, the result is infinitely better than is that obtained by any other method, and there is an enormous saving of time to the patient.

*Dr. Richard L. Igel, Jr., of Leavenworth, Kansas, says:*

In the treatment of patellar fracture the method of procedure is largely dependent on the character of the injury present. If due, as is most frequently the case, to sudden, violent action of the quadriceps extensor muscle, the line of division is transverse, the aponeurotic covering is usually torn, and there is considerable space intervening between the two fragments. If occurring as the result of direct violence the fracture is more often vertical or star shaped, the aponeurosis remains intact, and there is but slight displacement, as a rule. The simple fractures where the capsule remains unruptured are best treated without operative interference. The most satisfactory results can be secured by the use of a long posterior splint, with attached foot rest. Above and below the injured bone half inch strips of adhesive plaster are attached, transversely, and to the ends of these, on either side, pieces of strong elastic webbing are fastened, the loose extremities of which pass to sharp tongued buckles on the sides of the splint. These elastics are so arranged as to exert tension on the upper and lower fragments, bringing them in apposition. The apparatus is a modification of one devised by Manning, and, in my experience, has proved very efficient.

Longitudinal and starred fractures with unbroken capsule, and consequent slight separation, require only the posterior splint for from two to five weeks, coupled with massage, then passive movement, succeeded by careful exercise.

In transverse fractures of the more severe type, unless operation is contraindicated by some intercurrent disease or the patient prefers an impaired limb during the remainder of his life to the risk attendant on instrumental interference, operative measures are invariably indicated. The date at which the operation should be undertaken depends on the condition of the surrounding structures. If these are considerably involved, or a synovitis present, a wait of from one to two weeks, with rest and the application of cold, locally, is necessary.

If considerable serum has exuded into the joint aspiration is indicated.

The bone is exposed by a transverse, semilunar incision, extending about one inch above the upper border of the superior fragment, and the flap carefully dissected down. The blood clots are removed with a spoon, all intervening ligamentous and tendinous structures cleared away, and the fragments coapted. Absolute asepsis is essential to success. The use of strong, irritating antiseptics is to be avoided. I prefer a solution of carbolic acid or lysol. If there is much fragmentation the edges of the capsule are now drawn together, not too tightly, with chromicized catgut sutures, and the outer wound closed, small gauze drains being inserted bilaterally at the corners. Sometimes a circumferen-

tial suture of small kangaroo tendon will prove of value here, especially if there has been much comminution.

If the bone is divided into only two or three pieces the most satisfactory results can be secured by using two, or, at most, four, fine chromicized kangaroo or medium catgut ligatures, and passing them through slanting holes, drilled about one fourth of an inch back from the fractured margin. These bind the mass together efficiently, give rise to no irritation, and never cause secondary joint trouble. It is usually well, in all of these cases, to freshen the opposing edges of bone with a sharp curette before bringing the parts together. The wound having been covered with a moist antiseptic dressing (it is best to take no chances of infection here), the limb is placed on a long, straight posterior splint and kept elevated. At the end of one week the dressing can be changed, and the stitches and drainage wicks taken out.

Later the splint should be frequently removed and the part massaged. The support can be completely discarded at the end of four weeks, and passive flexion commenced.

*Dr. G. Walther Otto, of Dresden, Germany, states:*

The most satisfactory treatment of fracture of the patella is the wiring of the broken bone. The physician who undertakes that operation must always bear in mind that the opening of the injured knee joint is a question of life and death to the patient. Only those who master asepsis in every detail are competent to perform this operation.

Besides the operator, two assistants are necessary, one to give the narcotic, another one to assist during the operation. Both operator as well as his assistant must disinfect their hands very carefully and must wear sterile rubber gloves during the operation. The skin of the injured knee must be disinfected very carefully. Sterile napkins cover the limb and are fastened to the incision over the fracture with Miculicz clamps to make the contact of the hands of the operator and his instruments with the bare skin impossible.

The incision on the fracture should be vertical. All bleeding must be arrested. Examination of the opened joint will be done now. But no fingers in the joint! The assistant helps with sharp hooks. Blood clots are removed with sterile clamps or sterile gauze sponges, small pieces of the broken bone removed, etc. Do the operation as dry as possible. The operator helps himself to his well sterilized instruments and to the other utensils. The drilling of the holes through the broken bone must be done very carefully, to avoid splintering. The assistant holds the bone with forceps. By drawing the wire close together bring the broken parts of the patella as far as possible into their normal position. The wire must not irritate the cartilage surface of the articulation nor the skin. Overlapping fringes of periosteum ought to be laid over the united bone. Adapt the torn or cut ligaments and fascia by sutures and unite the skin incision exactly.

By paying minute attention to the rules of asepsis you will succeed. The slightly bent joint is dressed and placed in a stiff bandage from three to six weeks.

The necessity of changing the aseptic dressings and the condition of the patient will decide whether splints or plaster of Paris cast can be applied. At each change of the aseptic dressings great care has to be taken to avoid a secondary infection. Hands must be well disinfected, sterile rubber gloves used, and instruments and dressings sterilized.

After removal of the stiff bandages the physician begins the passive movements of the joint. To restore active power and nutrition of the muscles of the leg after the enforced quiescence, massage very soon.

### Therapeutical Notes.

**Lotions for Seborrhœic Eczema of the Scalp.**—Resorcin has been found remarkably efficacious in controlling seborrhœic eczema of the scalp—the condition of the scalp characterized by the appearance of what is popularly termed “dandruff.” In the following lotion the resorcin is exhibited in an agreeable form, the prescription being taken from *Die Praxis der Hautkrankheiten*, a collection of the teachings of Unna:

R. Castor oil, .....	5i.
Resorcin, .....	5iiss.
Eau de Cologne, .....	5iii.
Alcohol (95 per cent), .....	5ix.

M. ft. lotio.

This may be used as a hair wash applied to the scalp two or three times a week.

L. Duncan Bulkley uses a stronger solution of resorcin in a different menstruum, prescribing the following:

R. Resorcin, .....	5ii.
Alcohol, .....	5iii.
Glycerin, .....	5iv.
Rose water, .....	q. s. ad 5iv.

M. ft. lotio.

This is directed to be applied by means of a long “hair dropper,” and thoroughly rubbed in, with shampooing every week or so.

**Nitrite Poisoning Following Large Doses of Bismuth Subnitrate.**—Two recent cases of death following the internal administration of bismuth subnitrate in the large doses required for radioscopic purposes prompt us to caution in the use of this substance. It would seem that the salt is reduced in the system by bacterial reaction, both nitric acid and nitrites being formed in the blood in sufficient quantity to cause death. In *The Therapeutic Gazette*, for April, 1908, a citation is made from an article by A. Böhme (*Archiv für experimentelle Pathologie und Pharmacologie*, lvii, 441, 1907) reporting the sudden death of an infant who had been given a bismuth solution by mouth and later also by rectum. Three hours after the rectal injection she was seized with abdominal pains, vomiting and diarrhœa, cyanosis, which steadily became more marked, dyspnea, collapse symptoms, and death within thirty minutes of the onset. These it will be noted are not the symptoms of bismuth poisoning *per se*, which it is well known more nearly resemble those of mercurial poisoning. In the other case reported by Bennecke and Hoffmann the drug had been given in butter-milk and it was supposed that death had been caused by the absorption of the salt

through its dissolution in the lactic acid of the milk, but this did not explain the methæmoglobinæmia found at the autopsy. In Böhme's case the most evident post mortem finding was also methæmoglobinæmia, and he set himself the task of determining experimentally if sufficient nitrites could be produced and absorbed from bismuth subnitrate to endanger life. He seems to have established by chemical means and by experiments on animals that such is the case. He found that human fæces was capable of reducing nitrates to nitrites, and the reaction occurred more readily and frequently with infant stools, than with the fæces of adults. From this he thinks it possible that the combination of a large quantity of the bismuth salt with a pronounced bacterial activity might produce sufficient amounts of the nitrites to cause a methæmoglobinæmia, but, at the same time, he believes that therapeutic doses of bismuth subnitrate are not capable of producing harm in human beings, even in the very young. The large doses which are required for radiography should be used with some caution even in adults, especially as the conditions favoring nitrite production are not well understood. It has been proposed to substitute bismuth hydroxide for the subnitrate, a step which would exclude the possibility of nitrite poisoning.

**Gargles for Sore Throat.**—Where there is only a slight degree of inflammation a gentle astringent preparation like the following is useful (*Bulletin général de thérapeutique*):

R. Sodium borate, .....	5ss.
Tincture of benzoin, .....	5ii.
Syrup of mulberry, .....	5v.
Water, .....	5vi.

M. ft. gargarisma.

A ten per cent. solution of borax in glycerin used as a mouth wash leaves a clean, soothing sensation.

As soon as the acute symptoms have subsided it is recommended to employ a stronger topical application and thus insure a good healthy condition of the parts. M. Lermoyes (*loc. cit.*) prescribes the following:

R. Sodium borate, .....	gr. xlv.
Resorcin, .....	gr. xlv.
Glycerin, .....	5vss.
Peppermint water, .....	5i.

M.

**Injection for Multiple Sclerosis.**—Botéano (*Journal de médecine de Paris*, April 4, 1908) gives every second or third day a hypodermatic injection of fifteen minims of the following solution:

R. Saponin, .....	gr. i. s.
Distilled water, .....	5i.
Cherry laurel water, .....	5v.

M.

The treatment should be suspended if symptoms of intolerance are shown, such as mydriasis, dryness of the throat, sleeplessness, etc.

**Pyelitis.**—Robin prescribes the following pill in inflammation of the mucous membrane of the pelvis of the kidney:

R. Acacia, .....	5ss.
Camphor, .....	5iiss.
Extract of opium, .....	gr. ss.
Extract of opium, .....	gr. i.

M. ft. pil. lx.

Sup. One pill two or three times a day.

NEW YORK, SATURDAY, MAY 9, 1908.

TYPHOID FEVER IN MILITARY AND  
INDUSTRIAL AGGREGATIONS.

The May number of the *Military Surgeon* contains a number of valuable articles expository of certain points in connection with typhoid fever as it prevails among men gathered together in close quarters, whether for military or for industrial purposes. It seems to have been due to some extent to deference to the teachings of so excellent an observer as Sir Patrick Manson (which teachings may have been misunderstood) that in the Philippine Islands some outbreaks of typhoid fever have for a time failed of recognition, the disease being spoken of as "simple" and "double" continued fever—"simple" denoting cases without a relapse, and "double" being applied to those with a relapse. Another source of error has lain in undue importance being attached to the absence of Widal's agglutination reaction before convalescence was established.

The first of the articles referred to is by Lieutenant Henry J. Nichols, an assistant surgeon in the army, most of whose observations were made in the post hospital of Camp Bumpus, Tacloban, Leyte. Dr. Nichols is of the opinion that typhoid fever—popularly known in the Philippines simply as a variety of *calentura*—is much more prevalent among the natives, especially the children, than is generally supposed. In this opinion he has the support, by no means negligible, of the intelligent Spanish father of one of his little patients. The man declared, in answer to a question, that the disease with which his child was afflicted was *regu-*

*lar y natural en todos los pueblos y barrios* of that part of Leyte.

Dr. Nichols further concludes that cases resembling the "simple" and "double" continued fever of Crombie and Manson should not be regarded as entities, but as examples of simple and relapsing typhoid fever; that the Widal test cannot be depended on for a diagnosis unless the reaction occurs, for it may fail to show the expected result until the fourth week or even until convalescence has set in; and that the mortality from typhoid fever among white persons in the Philippines is not excessive.

The next article is by Lieutenant Earl H. Bruns, an assistant surgeon in the army, on an epidemic of typhoid fever in Iloilo. Dr. Bruns's experience with the Widal test coincides with that of Dr. Nichols. He reports that the epidemic was confined to one company of the Eighth Infantry, and to that part of the company which was lodged in a structure that is supposed to have become infected, the supposition being supported by the subsidence of the epidemic when the structure had been fumigated and disinfected.

The third article is by Lieutenant Colonel Louis A. La Garde, deputy surgeon general, who, commenting on the epidemic described by Dr. Bruns (the second one, it seems), says: "The laboratory assistant had failed to obtain the Widal reaction. Nevertheless, rose colored spots and enlargement of the spleen were associated in the majority of cases. These symptoms, with the fever, even in the absence of the agglutination test, should have been sufficient to warrant a diagnosis of typhoid fever; to wait for confirmation by a delayed Widal reaction under such circumstances was simply adding to the spread of the disease."

Captain Louis C. Duncan, an assistant surgeon in the army, contributes an interesting account of a small typhoid epidemic in the county of Missoula, Montana, in a succession of camps of laborers engaged in railway construction. They were "laborers of the lowest class, from all parts of the country, living in tents and temporary houses, with no sanitary arrangements or control." Dr. Duncan says: "The large contractors employed physicians to treat the sick and injured, but no sanitary officers to prevent sickness." "Here," he adds, "was to be seen the working of the idea prevalent in the army until recently, that medical men were employed to cure sickness, not to prevent it." He thinks that the infection was chiefly in the drinking water, which, though originally pure, is contaminated in the irrigation ditches, which pass through "fields, pastures, barnyards, hog lots, and other sources of filth and infection." Flies are not numerous, and practically there is no wind, and consequently but little dust in the air.

## GREAT MEDICAL LIBRARIES.

The librarian of the New York Academy of Medicine has compiled a list of the considerable medical libraries of the world, and it has been published by the American Medical Association. In most instances the size of the library is stated. Among the larger collections are the following: The New York State Medical Library, Albany, 18,912 books; the Medical Library of the University of Michigan, Ann Arbor, 19,165; the Library of the Medical and Chirurgial Faculty of Maryland, Baltimore, 17,103; the Library of the Kaiser Wilhelm Academy for Military Medical Training, Berlin, 65,000; the Library of the Berlin Medical Society, 30,000; the Boston Medical Library, 57,493; the Bristol (England) Medical Library, 21,000; the Library of the Medical Society of the County of Kings, Brooklyn, 65,000; the Library of the Academy of Medicine of Belgium, Brussels, 100,000; the Library of the Royal Society of Physicians of Budapest, 20,528; the Library of the Medical College of Bengal, Calcutta, 50,000; the Medical Section of the John Crerar Library, Chicago, 42,000; the Library of Rush Medical College, University of Chicago, 16,000; the Cincinnati Hospital Library, 18,000; the Library of the Royal College of Physicians of Ireland, Dublin, 15,000; the Library of the Royal College of Surgeons in Ireland, Dublin, 30,000; the Library of the Royal College of Physicians of Edinburgh, 80,000; the Library of the Royal College of Surgeons, Edinburgh, 15,000; the Library of the Royal Medical Society, Edinburgh, 30,000; the Medical Library of the Scientific School, Florence, 30,000; the Library of the College of Physicians and Surgeons of Glasgow, 50,000; the Medical Library of the Imperial University, Kyoto, 25,016; the Library of the British Medical Association, London, 20,000; the Library of the Medical Society of London, 25,000; the Library of the Royal College of Physicians, London, 25,000; the Library of the Royal College of Surgeons of England, London, 60,000; the Library of the Royal Society of Medicine, London, 70,000; the Library of the Manchester (England) Medical Society, 37,310; the Library of the Bureau of Science, Manila, 25,000; McGill Medical Library, Montreal, 30,000; the Library of the New York Academy of Medicine, 85,000; the Library of the Paris Academy of Medicine, 100,000; the Library of the Faculty of Medicine of Paris, 175,000; the Library of the College of Physicians of Philadelphia, 84,423; the Library of the Habermann Medical College, Philadelphia, 15,000; the Medical Library of the Pennsylvania Hospital, Philadelphia, 15,000; the Library of the Rhode Island Medical Society, Providence, 22,000; the Library of the Imperial Academy of Medicine, St.

Petersburg, 170,000; the Lane Medical Library, San Francisco, 33,000; the Caroline Institute Library, Stockholm, 40,000; the Library of the Surgeon General's Office, United States Army, Washington, 158,791; the Library of the United States Naval Medical School, Washington, 16,000.

In our enumeration we have omitted mention of libraries containing fewer than 15,000 books each. It will be seen that the largest collection is in Paris. Then come those in St. Petersburg, Washington, Brussels, New York, Philadelphia, and Edinburgh. Particularly noteworthy is the rapid growth of the Library of the Bureau of Science, in Manila, which must have been started less than ten years ago. The Library of the Medical Society of the County of Kings, too, has grown very rapidly within the last few years. Such increments betoken a gratifying appreciation of the value of libraries in the diffusion of knowledge. There are, indeed, few agencies, if any, on which greater dependence can be placed for the spread of medical knowledge. The growth of medical libraries should on all accounts be promoted to the full ability of the profession.

## THE DIAGNOSIS OF CANCER OF THE TONGUE IN SYPHILITICS.

Far from being an exception, the coexistence of lingual syphilis and cancer is not uncommon, and probably syphilis is an important predisposing cause of malignant disease of the tongue, because it creates points of lessened resistance which favor the development of the neoplasm. The diagnosis of cancer should be made in syphilitic subjects by a careful study of all the symptoms. The pronounced induration of the ulceration, the appearance of a hard, everted edge, the amount of lymphatic involvement and pain, especially in the ears, when the case is one of lingual carcinoma, are all symptoms which should lead one to suspect cancer. On the other hand, if one is dealing with a purely syphilitic ulceration, these important symptoms are lacking. In the majority of cases carcinoma occurs in an old syphilitic presenting a localized lingual leucoplakia. The latter lesion remains for a considerable length of time in the form of brilliant white patches with a narrow red border, seated on the borders of the tongue or on its upper aspect, but little by little they become cracked and ulcerated. Up to this time there is nothing to call the patient's attention to it, but sooner or later the surface of the patch becomes irregular, and is covered by warty projections. These papillomatous vegetations take on the aspect of a cat's tongue, and are the indication of an imminent transformation of the leucoplakia into cancer. When this has taken place, a hard tumor will

be found, usually on the point of ulcerating, and from the very beginning of this transformation the patient experiences sharp pain, extending toward the ear. When salivation sets in, with fœtor of the breath, the diagnosis can no longer be faulty. In other cases the carcinoma occurs in a syphilitic in the full tertiary period.

In gummatous glossitis the malignant growth becomes grafted on a gumma which has broken down, and here its aspect is very typical. On a tongue presenting rounded, hollow ulcers, with sharply cut borders, in the midst of thickened tissues will be seen on the dorsal aspect of the organ, usually toward its centre, one of these ulcerations, bleeding easily and secreting a bloody liquid. The borders are only slightly undermined, but are not sharply cut. The base of the ulcer is covered with a grayish adherent membrane as in a gumma; if the growth is pressed, little fragments of tissue may be squeezed out, a most important symptom in favor of carcinoma. The diagnosis may also be based on the presence of enlarged glands, pain, and salivation.

If one is dealing with a sclerogummatous tongue, the clinical picture changes. Only infrequently does the malignant growth precede the syphilitic manifestations in the tongue in this case, and should they develop together the cancer will awaken the old syphilitic process. But usually the sclerogummatous process and cancer are associated. The tongue increases in size, presenting quite a large induration at a given point. Then a cancerous ulceration is not long in appearing, while the condition of the glands will give evidence of its malignancy. Quite different is the evolution of carcinoma in a syphilitic subject who is cured. In point of fact, syphilis, by its sclerosing action on the tissues, prepares a poor soil for the development of carcinoma.

#### ANCIENT HEPATOSCOPY.

In the twenty-ninth volume of the third series of the *Transactions of the College of Physicians of Philadelphia*—a volume which, like its predecessors, is replete with valuable matter—we find an article on a subject so unusual that it is likely to appeal particularly to those who are interested in the history of medicine, including its connection with the mysticism of times long gone by. It is entitled *The Liver in Antiquity and the Beginnings of Anatomy*, and its author is Morris Jastrow, Jr., Ph. D., professor of semitic languages in the University of Pennsylvania.

Professor Jastrow deals largely with divination by inspection of the liver of sacrificial animals, as practised by the ancient Babylonians and other peoples of remote antiquity. He traces a connection

between this ancient hepatoscopy, or hepatomancy, which has met with oblivion, and palmistry, which, though itself ancient, has survived and still figures in the belief of many thousands of persons, some of whom are intelligent and otherwise rational. Moreover, this old form of divination by minute observation of the hepatic fissures doubtless played a part in leading to the subsequent scientific study of the anatomy of the liver.

#### DEEP PERICARDITIS.

This term seems preferable to "subpericarditis" (*sous-péricardite*), under which name M. Babes made the affection the subject of certain remarks at a recent meeting of the Paris Society of Biology (*Semaine médicale*, April 1st). It is described as an inflammation and degeneration of the deep portions of the pericardium and of the superficial part of the underlying muscular tissue of the heart, occurring particularly as a complication of pulmonary emphysema, chronic bronchitis, ulcerative pleuropneumonia, etc. It is said to be rather frequent, having been observed nineteen times in a hundred and fifty post mortem examinations, and seven times among thirty-five cases of such heart diseases as endocarditis and myocarditis. The lesions are incontestable, though they are not very apparent to the naked eye, and M. Babes has no doubt that they count in the production of pericarditic and myocarditic phenomena. He himself has seen four cases of a grave character in which no other cardiac lesions were made out.

#### A NEW LARYNGOLOGICAL JOURNAL.

We have received the first number of the *Zeitschrift für Larynologie, Rhinologie und ihre Grenzgebiete*, edited by Dr. Felix Blumenfeld, of Würzburg, and published by Curt Kabitzsch, of Würzburg. It is announced that a volume will appear every year, in six parts, which will be published about every second month. Under *Grenzgebiete* are understood tracheoscopy, bronchoscopy, œsophagoscopy, diseases of the mouth, diseases of the cavities of the head, including the orbit, the external surgery of the throat, the pathology and therapeutics of the voice, and diseases of the lungs and skin, so far as all these affections have any connection with those of the larynx and nose. The first number contains articles by Dr. P. Heymann and Dr. G. Ritter, of Berlin; Dr. Voigt, of Würzburg; Dr. Alexander Iwanoff, of Moscow; Professor Gerber, of Königsberg; Professor Kan, of Leyden; Dr. Hansberg, of Dortmund; Dr. Möller, of Copenhagen; Professor Starck, of Karlsruhe; Dr. Goris, of Brussels; and Dr. Herman Gutzmann, of Berlin.

## THE DOCTOR'S DUTY TO THE STATE.

Under this title a well known Philadelphia surgeon, Dr. John B. Roberts, has recently issued a pamphlet in which are printed various addresses of his dealing with certain matters of ethics. The collection deserves to be studied by the medical profession. Some practices that meet with more or less general toleration are clearly shown by Dr. Roberts to be unworthy of a liberal profession and detrimental to the welfare of the community. Even those who already realize the truths which he enunciates may gather from the pamphlet effective arguments to use for the enlightenment of those who do not as yet realize them.

### News Items.

**Changes of Address.**—Dr. Walter C. Gilday, to 44 West Thirty-seventh street, New York; Dr. Charles B. Warden, to 322 South Sixteenth street, Philadelphia.

**The Pennsylvania Red Cross Society** sent six nurses to the tornado district in the South on Friday, May 1st. The nurses were graduates of the Medico-Chirurgical Hospital Training School, Philadelphia.

**The Northwestern Medical Association of Philadelphia** met on Friday evening, May 8th. The principal paper of the evening was read by Dr. E. E. Montgomery on Office Treatment of the Diseases of Women.

**The Alumni Association of Carney Hospital, Boston,** held its annual meeting and banquet on the evening of April 23d. Officers were elected as follows: President, Dr. F. X. Crawford; vice president, Dr. John T. Sullivan; and secretary, Dr. W. H. Burke.

**American Gastroenterological Association.**—The eleventh annual meeting of this association will be held in Chicago on Monday and Tuesday, June 1 and 2, 1908. The sessions will be held at the Auditorium Hotel, and all members of the medical profession are cordially invited to attend.

**National Confederation of State Medical Examining and Licensing Boards.**—The annual meeting of this organization will be held at the Lexington Hotel, Twenty-second street and Michigan Boulevard, Chicago, on Monday, June 1st. There will be three sessions, at 10 a. m., 2 p. m., and 8 p. m., respectively.

**The Mortality of New Orleans.**—During the month of March, 1908, there were 633 deaths reported from all causes, 386 white and 247 colored. The annual death rate in 1,000 of population was 17.91 for the white population, 31.87 for the colored, and 21.64 for the total white and colored. There were 48 still births.

**American Medical Editors' Association.**—The annual meeting of this society will be held at the Auditorium Hotel, Chicago, on May 30th and June 1st. An extensive and interesting programme has been prepared, and every member of the association is urged to be present. Editors of medical publications who are not affiliated with the society are also invited to attend.

**The Buffalo Academy of Medicine.**—A meeting of the Section in Surgery was held on the evening of May 5th. The principal feature of the programme was a paper by Dr. Paul Thordmike, professor of genitourinary diseases at the Harvard Medical School, on Patients with Enlargement of the Prostate Who Should Not be Operated upon by Prostatectomy.

**Contagious Diseases in Chicago.** During the week ending April 25th there were reported to the Department of Health 607 cases of communicable diseases. Of these 16 were diphtheria, 78 were scarlet fever, 7 were smallpox, 326 were measles, 28 were chickenpox, 25 were typhoid fever, 21 were whooping cough, 41 were tuberculosis, and 12 were contagious diseases of minor importance.

**National Association for the Study of Epilepsy and the Care and Treatment of Epileptics.**—The annual meeting of this association will be held in Indianapolis, Ind., on Tuesday and Wednesday, November 10 and 11, 1908. Those desiring to attend the meeting and present papers should communicate with Dr. J. F. Munson, secretary and treasurer, Craig Colony for Epileptics, Sonoma, N. Y.

**The Northwestern Medical Society, Philadelphia.**—At a meeting of this society, held on Monday, May 4th, the general subject for discussion was the rights of the unborn child. The subject was dealt with from the standpoint of the law by John M. Patterson, LL. B.; from the standpoint of the church by the Rev. Joseph J. Murphy, D. D., J. C. D.; and from the standpoint of the physician by Dr. Wilmer Krusen.

**A Meeting of Officers of Hospitals for the Insane.**—The semiannual meeting of the trustees and superintendents of the State and Incorporated Hospitals for the Insane and Feeble-minded of Pennsylvania was held in Philadelphia on Tuesday afternoon, May 5th. The programme included a paper entitled Some Questions Relating to the Insane, by Dr. Robert H. Chase, and a paper on the Potentially Insane, by Dr. Frank Woodbury.

**A Tuberculosis Sanatorium in Rensselaer County, N. Y.**—At the regular monthly meeting of the Medical Society of the County of Rensselaer, N. Y., which was held in Troy on Tuesday, April 14th, the following resolution was adopted: "Resolved, that it is the sense of every member of the Medical Society of the County of Rensselaer that a county sanatorium and hospital be erected for the care of advanced tuberculosis cases."

**Wills Hospital Ophthalmic Society, Philadelphia.**—The following papers were presented at a meeting of this society, which was held on Monday afternoon, May 4th: The Value of Photography in Ophthalmology, by Dr. Frank C. Parker; A Case Illustrating the Results of Iridotomy, by Dr. George Robinson; Tenotomy of the Inferior Oblique, by Dr. William Campbell Posey; Some Results of Galvanocautery Puncture, by Dr. S. Lewis Zeigler.

**Syracuse, N. Y., Academy of Medicine.**—A meeting of this academy was held on the evening of May 5th. Dr. I. H. Levy read a paper entitled The Diagnosis of Gallstones, and Dr. Clarence E. Coon read a paper on the X Ray as an Aid in the Early Diagnosis of Pulmonary Tuberculosis, which was illustrated with lantern slides. Dr. A. B. Miller opened the discussion on Dr. Levy's paper, and Dr. A. C. Mercer opened the discussion on Dr. Coon's paper.

**Scientific Society Meetings in Philadelphia for the Week Ending May 16, 1908.**—*Monday, May 11th.* Section in General Medicine, College of Physicians; Wills Hospital Ophthalmic Society. *Tuesday, May 12th.* Philadelphia Pediatric Society; Botanical Section, Academy of Natural Sciences. *Wednesday, May 13th.* Philadelphia County Medical Society. *Thursday, May 14th.* Section Meeting, Franklin Institute. *Friday, May 15th.* American Philosophical Society.

**Appointments at the Northwestern University Medical School, Chicago.**—Dr. John B. Murphy has resigned as professor of surgery and co-head of the department in Rush Medical College, and has accepted the position of professor of surgery and head of the department in Northwestern University Medical School. Dr. A. W. Meyer, of the University of Minnesota, has accepted the professorship of anatomy, and Dr. A. N. Richards, of the College of Physicians and Surgeons, New York, has been appointed professor of pharmacology.

**The Harvey Lectures.**—The tenth and last lecture in the Harvey Society course will be delivered at the New York Academy of Medicine on Saturday, May 9th, at 8:30 p. m., by Professor A. E. Schafer, of the University of Edinburgh. The subject of the lecture is Artificial Respiration in Man. Professor Schafer was chairman of a committee appointed by the Royal Medical and Chirurgical Society to investigate the phenomena attending death by drowning and the means of promoting resuscitation in the apparently drowned, and his lecture will embody the results of much practical work on the subject of artificial respiration. Professor Schafer came to the United States for the purpose of giving the Hunter lectures at the Johns Hopkins Medical School.

**American Laryngological Association.**—The thirtieth annual congress of this association will be held in Montreal, Canada, on May 11, 12, and 13, 1908. The headquarters of the association will be at the Windsor Hotel. An excellent programme has been prepared and ample arrangements have been made for the entertainment of the visiting members and their friends. The meeting promises to be one of great interest, and all members of the medical profession are cordially invited to attend.

**New York Academy of Medicine.**—At a stated meeting of the academy, held on Thursday evening, May 7th, under the auspices of the Section in Public Health, Dr. Walter Benschel, sanitary superintendent of the New York Department of Health, read a paper entitled Possible Sources of Typhoid Fever in New York City. Among those who took part in the discussion were Dr. E. G. Janeway, Dr. A. Seibert, Dr. J. M. Wainwright, Dr. William H. Park, and Dr. John S. Thacher.

**The Floyd County, Ga., Medical Society.**—The Seventh District Branch of this society met in Rome on March 11th and effected a permanent organization, with the following officers for the ensuing year: President, Dr. R. P. Cox, of Rome; vice president, Dr. C. F. McLaird, of Calhoun; secretary and treasurer, Dr. Harlan L. Erwin, of Dalton. The society meets twice a year, on the second Wednesday in October and March. The next meeting will be held in Cartersville on October 14th.

**Pennsylvania Society for the Prevention of Social Disease.**—A meeting of this society will be held at the College of Physicians, Philadelphia, on May 22d, at which Dr. Helen C. Putnam, of Providence, R. I., will deliver an address outlining her experience in the teaching of hygiene and morality in the public schools. Dr. Putnam is chairman of the Committee on the Teaching of Hygiene in the Public Schools, appointed by the American Academy of Medicine. The meeting will be open to the public.

**American Laryngological, Rhinological, and Otolological Society.**—The fourteenth annual meeting of this society will be held in Pittsburgh, Pa., on May 28, 29, and 30, 1908. The headquarters of the society will be at the Hotel Schenley, and the sessions will be held in the Carnegie Library. The programme, which seems to be a particularly good one, includes a "symposium" on the cosmetic and plastic surgery of the nose, throat, and ear. The oration in otology will be delivered by Dr. A. Jansen, of Berlin, Germany. All members of the medical profession are invited, and a good time is expected.

**The Obstetrical Society of Philadelphia.**—A stated meeting of this society was held on the evening of May 7th. The programme, which was a long one, included the following papers: The Toxæmia of Pregnancy, by Dr. Collin Foulkrod; A Case of Concealed Hemorrhage in Pregnancy compared with a Case of Extrauterine Pregnancy, by Dr. George Erety Shoemaker; The Value of Acetone in the Treatment of Inoperable Carcinoma Uteri, by Dr. F. Hurst Maier; Drainage of the Pelvic Cavity after Abdominal Section, by Dr. Ella B. Everitt; Hypernephroma, by Dr. L. J. Hammond.

**College of Physicians of Philadelphia.**—A stated meeting was held on the evening of May 6th. Dr. Meyer Solis-Cohen read a paper on a Simple and Accurate Method for Testing the Clotting Time of the Blood. Dr. Warren Walker read a paper on Myositis Ossificans Progressiva, and exhibited a patient with the disease. Dr. Gwilym G. Davis presented several patients with congenital dislocation of the hip. A paper by Dr. John H. Jopson, Dr. C. Y. White, and Dr. John Speese on Tumors of the Breast in Childhood was presented, and Dr. Henry Tucker read a paper on the Local Uses of Solutions of Magnesium Sulphate in the Treatment of Erysipelas.

**The Mortality of Chicago.**—According to the report of the Department of Health for the week ending April 25, 1908, there were during the week 623 deaths from all causes, as compared with 678 for the corresponding period in 1907. The annual death rate in 1,000 of population was 19.00. The principal causes of death were: Apoplexy, 11; Bright's disease, 48; bronchitis, 19; consumption, 78; cancer, 23; convulsions, 6; diphtheria, 8; heart diseases, 47; influenza, 6; intestinal diseases, acute, 40; measles, 7; nervous diseases, 19; pneumonia, 112; scarlet fever, 5; suicide, 11; typhoid fever, 3; violence, other than suicide, 26; whooping cough, 1; all other causes, 142.

**Personal.**—Dr. George H. Kirby has resigned as associate in clinical psychiatry at the Pathological Institute of New York, and has accepted the position of director of clinical psychiatry at the Manhattan State Hospital, Ward's Island, N. Y.

Dr. Llewellyn F. Barker, professor of medicine at the Johns Hopkins Medical School, has received the honorary degree of doctor of laws from Queen's University, Kingston, Ontario.

Dr. William H. Warren has been chosen dean of the Medical Department of Washington University, St. Louis, to succeed Dr. Robert Luedeking, who died recently.

**New York Pathological Society.**—The regular meeting of this society will be held at the Academy of Medicine on Wednesday evening, May 13th, at 8:30 o'clock. The programme includes the following papers: Two Atypical Kidney Tumors, by Dr. I. Strauss; A Case of Rhabdomyoma of the Tongue, by Dr. Horst Oertel; Notes on Blood Cultures in Glanders, by Dr. B. Crohn; The Agglutinating Action of Ricin on Erythrocytes in Isotonic Sugar Solution, by Dr. Cyrus W. Field; Report on a Series of Tumors of the Rat and Mouse, with demonstrations, by Dr. Simon Flexner and Dr. J. W. Jobling; Prevention by Atoxyl of Syphilis in Macacus Rhesus, by Dr. Simon Flexner.

**Mortality Statistics of New York.**—During the week ending April 25, 1908, there were reported to the Department of Health of the City of New York 1,536 deaths from all causes, as compared with 1,671 for the corresponding period in 1907. The annual death rate was 18.12 in 1,000 of population. Of the total number of deaths 801 were in Manhattan, 140 in the Bronx, 520 in Brooklyn, 57 in Queens, and 18 in Richmond. The principal causes of death were: Apoplexy, 58; Bright's disease and nephritis, 113; bronchitis, 32; cancer, 65; contagious diseases, 153; diarrheal diseases, 44; diarrheal disease, under five years of age, 43; pneumonia, 262; organic heart diseases, 148; pulmonary tuberculosis, 180; tuberculosis, other than of the lungs, 34; typhoid fever, 11; suicide, 24; homicide, 3; accidents, 59. There were 119 still births.

#### Infectious Diseases in New York:

*We are indebted to the Bureau of Records of the Department of Health for the following statement of new cases and deaths reported for the two weeks ending May 2, 1908:*

	—April 25—		—May 2—	
	Cases.	Deaths.	Cases.	Deaths.
Tuberculosis pulmonalis . . . . .	439	180	432	178
Diphtheria . . . . .	344	39	425	45
Measles . . . . .	1,891	39	1,652	41
Scarlet fever . . . . .	929	64	855	60
Smallpox . . . . .	..	..	..	..
Varicella . . . . .	153	..	158	..
Typhoid fever . . . . .	33	11	36	8
Whooping cough . . . . .	14	1	27	..
Cerebrospinal meningitis . . . . .	12	7	12	14
Totals . . . . .	3,815	341	3,648	346

**Colleges and Hospitals Cooperating in Educational Work.**—At a meeting of the Hospital Conference of the City of New York, held at the Academy of Medicine on April 30th, a report of the sub-committee on medical organization and medical education was presented. The committee reported that the faculties of Cornell University Medical College, University and Bellevue Medical College, and the College of Physicians and Surgeons had all agreed that the time had arrived for the readjustment of the curriculum of the medical schools so as to enable the fourth year, or graduating class, to spend additional time in hospital wards as clinical clerks and surgical dressers, or as students participating in the work. At Cornell the faculty has already ordered that the hours from 10 a. m. to 12 m. shall be devoted to extramural teaching for as many students as can be at liberty at that time.

**The Annual Report of the Board of Trustees of the Philadelphia Polyclinic and College for Graduates in Medicine** has just been received. During the twenty-five years of the existence of the institution 15,500 patients have been treated in the hospital and 325,000 patients have been treated in the dispensaries. The following gifts were received during the past year: \$10,000 from the estate of Mary C. Dulles, \$5,000 from the estate of Louisa Dietrich, and \$2,400 from the Charity Ball Committee of 1907. Eighty-eight cases of typhoid fever were treated, with 5 deaths, a mortality of 5.65 per cent.; 59

cases of pneumonia and bronchopneumonia were treated, with 12 deaths, a mortality of 20.33 per cent.; 179 cases of intraabdominal disease were treated, with 19 deaths, a mortality of 10.61 per cent. There is no list of operations in the report, so that the mortality of operation cases cannot be computed. The report of the dean shows that during 1907, one hundred and fifty-eight students matriculated in the college department of the institution. Eight nurses were graduated from the training school during the year. The trustees report the necessity of temporarily stopping work on the new dispensary building, on account of lack of funds.

**Charitable Bequests.**—By the will of Lewis P. Simpson the Methodist Hospital of Philadelphia becomes a reversionary legatee, the money received to be used for the endowment of free beds and for the maintenance of the dispensary.

By the will of Charles H. Newhall, the Lynn, Mass., Hospital receives \$50,000, and the Old Ladies' Home and the Old Men's Home in Lynn receive \$15,000 each.

By the will of Sarah Reeves the Episcopal Hospital, Philadelphia, receives \$5,000 to endow a free bed in memory of Joel and Sarah P. Reeves, parents of the deceased. By the same will the Philadelphia Home for Consumptives receives \$500.

By the will of Patrick Larkin, Carney Hospital, Boston, receives \$5,000; Holy Ghost Hospital and Cambridge Hospital each receive \$1,000.

**A New National Hospital for Cuba.**—Hospital de Alfonso XIII, which was originally built in 1895, is to be rebuilt on the heights of Principe Castle, just outside of the city of Havana. Plans for a two story building have been filed, and the work will be begun as soon as Governor Magoon issues the necessary financial decrees. The present available fund consists of a balance in hand of \$120,000 from the fund granted by the Cuban congress and a grant of \$150,000 from Governor Magoon. The Cuban congress also voted an annual subsidy of \$150,000 until a total of \$750,000 had been collected. Governor Magoon will confirm this latter arrangement, thus giving the board an available fund of \$1,000,000 for the building and equipment of the hospital. It is the intention of the board to make this hospital thoroughly modern in every respect, and no effort is being spared in the search for the latest and best surgical and pharmaceutical equipment. The question of having a department for the study of tropical medicine connected with the hospital is under advisement.

**The Health of Philadelphia.**—During the week ending April 18, 1908, the following cases of transmissible diseases were reported to the Bureau of Health of Philadelphia: Typhoid fever, 79 cases, 13 deaths; scarlet fever, 75 cases, 3 deaths; chickenpox, 36 cases, 0 deaths; diphtheria, 71 cases, 12 deaths; cerebrospinal meningitis, 8 cases, 5 deaths; measles, 424 cases, 9 deaths; whooping cough, 22 cases, 9 deaths; pulmonary tuberculosis, 140 cases, 45 deaths; pneumonia, 74 cases, 65 deaths; erysipelas, 4 cases, 2 deaths; puerperal fever, 4 cases, 3 deaths; mumps, 37 cases, 0 deaths; cancer, 16 cases, 23 deaths; septicæmia, 2 cases, 0 deaths. The following deaths were reported from other transmissible diseases: Tuberculosis, other than tuberculosis of the lungs, 11; diarrhoea and enteritis, under two years of age, 13. The total deaths for the week numbered 496, in an estimated population of 1,532,738, corresponding to an annual death rate of 16.80 in 1,000 of population. The total infant mortality was 117; under one year of age, 87; between one and two years of age, 30. There were 53 still births; 41 males, and 12 females.

**Changes in the Requirements for Admission to the College of Physicians and Surgeons, New York.**—The forthcoming announcement of this institution, which is the medical department of Columbia University, will contain notice of a change in the requirements for admission, to take effect in September, 1909. All candidates for the degree of doctor of medicine on entering the college will then be required to present a certificate from the Regents of the University of the State of New York, and must also show evidence of the completion of not less than two full years of study in an approved college or scientific school, or graduation from an approved college or scientific school; or a bachelor's degree or its equivalent from some approved European institution, or, in lieu of either of these, evidence of exceptional fitness to undertake the study of medicine. Candidates who have completed one or more years of study in an approved medical school will be ad-

mitted to advanced standing on presentation of proper certificates, provided that before beginning the study of medicine they have fulfilled the qualifications for admission required by the College of Physicians and Surgeons.

**Meetings of Sections of the New York Academy of Medicine.**—The Section in Neurology and Psychiatry will meet on Monday evening, May 11th, at 8:30 o'clock. After the presentation of patients and the reports of cases, Mr. Arthur Train, assistant district attorney, will read a paper entitled *Insanity as a Defense to Crime*. Among those who will take part in the discussion are Judge Dike, Bartow S. Weeks, Esq., Nathan A. Smythe, Esq., Dr. C. L. Dana, Dr. William Hirsch, Dr. William B. Pritchard, Dr. Smith Ely Jelliffe, Dr. James J. Walsh, and Dr. Carlos F. MacDonald.

The Section in Pædiatrics will meet on Thursday evening, May 14th, at 8:15 o'clock. Dr. Max G. Schlapp will report a case of cerebral changes following scarlatina and measles. Dr. Herman Schwarz will present a patient with infantilism and will read a paper entitled *Infantilism and Allied Conditions*, which will be followed by a general discussion.

A special meeting of the Section in Otology will be held on Tuesday, May 26th, to greet Mr. Arthur H. Cheate, F. R. C. S., of London. A buffet luncheon will be served at 2 p. m., and at 8:30 p. m. a lantern slide demonstration of Mr. Cheate's collection of temporal bones will be given in Hosack Hall. The collection will also be on exhibition on the afternoons and evenings of May 22d, 23d, and 25th.

**Prizes Offered for Members of the American Laryngological, Rhinological, and Otolological Society.**—Four prizes of \$100 each have been offered by members of the American Laryngological, Rhinological and Otolological Society, as follows:

By Dr. J. E. Sheppard for the best classification of non-suppurative affections of the middle ear, to be based as far as possible on pathological research.

By Dr. Charles W. Richardson for the best essay on the operative treatment which offers the best results for the cure of chronic suppurative frontal sinusitis.

By Dr. Norval H. Pierce for the best original work on rarification of the labyrinthine capsule.

By Dr. Edward R. Dench for the best essay on chronic non-suppurative inflammation of the middle ear.

The competition is open to members of the society only, and all essays must be in the hands of the secretary before April 15, 1909, who will furnish full information regarding the requirements. The council of the society also announces that the society holds a fund of \$500 for the encouragement of original research work. The whole, or a part, of this fund will be awarded, at the discretion of the council, to the member of the society presenting the best essay embodying original work in subjects relating to laryngology, rhinology, or otology.

#### Society Meetings for the Coming Week:

**MONDAY, May 11th.**—New York Academy of Medicine (Section in Neurology and Psychiatry); Society of Medical Jurisprudence, New York; New York Ophthalmological Society; Corning, N. Y., Medical Association; Waterbury, Conn., Medical Association.

**TUESDAY, May 12th.**—New York Academy of Medicine (Section in Public Health); New York Obstetrical Society; Newburgh Bay, N. Y., Medical Society; Buffalo Academy of Medicine (Section in Medicine); Medical Society of the County of Rensselaer, N. Y.; Medical Society of the County of Schenectady, N. Y.; Practitioners' Club of Jersey City, N. J. (annual).

**WEDNESDAY, May 13th.**—New York Pathological Society; New York Surgical Society; Medical Society of the Borough of the Bronx; Alumni Association of the City Hospital, New York; Brooklyn Medical and Pharmaceutical Association; Medical Society of the County of Richmond, N. Y.

**THURSDAY, May 14th.**—New York Academy of Medicine (Section in Pædiatrics); Brooklyn Pathological Society; Blackwell Medical Society of Rochester, N. Y.; Jenkins Medical Association, Yonkers, N. Y.

**FRIDAY, May 15th.**—New York Academy of Medicine (Section in Orthopedic Surgery); Clinical Society of the New York Post Graduate Medical School and Hospital; East Side Physicians' Association of the City of New York; New York Microscopical Society; Brooklyn Medical Society.

## Pith of Current Literature.

### THE BOSTON MEDICAL AND SURGICAL JOURNAL.

April 30, 1908

1. Some Urinary Infections with a Variety of the Staphylococcus Albus, By ARTHUR L. CHUTE.
2. The Treatment of Abnormal Rigidity of the Cervix Uteri by Deep Incisions. A Report of Two Cases, By NATHANIEL R. MASON.
3. Mattapan Day Camp for Consumptives, Boston, Mass., By DAVID TOWNSEND.
4. The Plaster of Paris Bar or Rope, By ROBERT SOUTTER.
5. Some Observations on a "Figure of Eight" Plaster Jacket, By JOHN D. ADAMS.

2. **The Treatment of Abnormal Rigidity of the Cervix Uteri by Deep Incisions.**—Mason reports two such cases. From his operations he concludes that where immediate delivery is demanded in the presence of an undilated and rigid cervix, multiple deep incisions from the border of the external os to the uterovaginal junction furnish the most rapid and safest method of emptying the uterus. There is no danger of the incisions tearing in cases under full term, or in cases at full term, where the pelvis is normal and the fetus is of moderate size, nor risk of hæmorrhage when clamps are employed before making the incisions. The chance of septic infection is no greater than after the lacerations occurring at the time of normal delivery, and the scars in the cervix and vaginal vault will cause no trouble in the course of subsequent pregnancies and labors.

4. **Plaster of Paris Bar or Rope.**—Soutter remarks that plaster of Paris bandages have been strengthened by strips of wood, steel, iron, cardboard, wood pulp, etc., and by laying the plaster gauze longitudinally instead of in a circular manner. The latter is not as rapid a manner of applying reinforcement as by means of the plaster bar or rope. To make a plaster bar, a very wet plaster of Paris bandage is rapidly unwound back and forth to the desired length. No attempt is made to rub it or to apply it to the partially applied dressing. When the roll is entirely unwound it is held at one end by one hand, while the other is grasped around it and slid down to the other end, moulding it into a bar. It is then slapped into place and rubbed three or four times. This method of reinforcement is more rapid than the time it takes to describe it, says the author. Plaster bars may be used in front and behind on a plaster of Paris spica at the weak points, or to strengthen a plaster jacket. In jackets for forcible correction in cases of curvature of the spine or bad round shoulders, it is often important to apply the jacket very rapidly. By means of two or four ropes a strong, light, and retentive apparatus can be finished in a very short time.

### THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

May 2, 1908

1. Chemical Problems in Hospital Practice, By OTTO FOHN.
2. The Scientific and Practical Value of Hospital Internship, By the Late NICHOLAS SENN.
3. Tuberculin in Pulmonary Tuberculosis, By PAUL H. RINGER.
4. Relationship between the Spinal Cord, the Sympathetic System, and Therapeutic Measures, By S. D. LUDLUM.

5. The Treatment of Placenta Prævia, By H. S. CROSSEN.
6. Practical Value of Modern Conceptions of Syphilis, By ALFRED SCHALEK.
7. Treatment of Eclampsia, By JOHN F. MORAN.
8. Some of the Motor Phenomena of Chorea Clinically Considered, By FRANK R. FRY.
9. Eye Syndrome of Dementia Præcox, By H. H. TYSON and L. PIERCE CLARK.

2. **The Scientific and Practical Value of Hospital Internship.**—This is the last paper prepared by the late Nicholas Senn, which was read for him. In it he said that one of the most valuable practical advantages of an internship is the association of his colleagues. A noble spirit of rivalry reigns in the little circle, a healthy stimulus for hard, honest work. Books and medical journals are read and their contents discussed. Cases and operations are made the subject of conversation at table and during hours of leisure, and this way each interne receives, to a certain extent, the benefits of the entire service, and such intercourse is the best possible preparation for their future work in medical societies. It is conducive to the development of the gift of debate and a wholesome spirit of criticism. Internes are attracted by medical societies, and often enrich the meetings by the presentation of cases and pathological specimens, thus filling in many gaps in the programme with valuable material. In this way the interne becomes at the very threshold a contributor to medical literature and learns the value of postgraduate education through the medium of medical societies.

### 3. Tuberculin in Pulmonary Tuberculosis.

—Ringer remarks that tuberculin may be employed in: 1. All incipient cases, cases of closed tuberculosis in which ulceration has not taken place and bacilli are not to be demonstrated in the sputum. 2. Uncomplicated, nonfebrile, first and second stage cases. 3. Fibroid cases not running a febrile temperature. 4. Febrile cases in which the temperature does not drop under treatment by rest, and where fever is due to the tuberculotoxine alone and not to mixed infection. In such cases tuberculin should be administered with the greatest caution, in the most infinitesimal doses, with long intervals between successive doses. 5. Advanced, third stage cases. Tuberculin can here occasionally be used, not as a curative agent, but to aid in relieving distressing symptoms. It will often relieve the tight, harassing cough that is so exhausting, render expectoration easier, do away with thoracic pain, and help to make the patient more comfortable. In such cases its administration should be most guarded and the dosage very minute. The contraindications are given as follows: 1. Greatly emaciated or greatly weakened individuals. The general body strength must first be raised by rest and proper diet before such patients will be able to supply those defensive forces which tuberculin stimulates to action. 2. Third stage cases with mixed infection. Those cases constitute the most absolute contraindications to the use of tuberculin. In them a hypersusceptibility is easily excited, violent reactions are prone to occur, a general aggravation of the symptoms may set in, and great harm result. 3. Hæmorrhage: Hæmoptysis occurring during the administration of tuberculin is a signal not for the permanent withdrawal of the

drug, but for its cessation at once and until some time after subsidence of all hæmorrhagic symptoms. 4. Heart disease: A contraindication only if it is feared that owing to possibility of reactions compensation may be lost. 5. Marked increase in pulse frequency, beginning and persisting during administration of tuberculin. 6. Marked loss of weight, beginning and persisting during the administration of tuberculin. 7. Complications: Diabetes, nephritis, hepatic cirrhosis, hysteria, neurasthenia, epilepsy. Of the results the writer remarks that patients tolerating increasing doses are not so prone to the exacerbations and relapses exhibited by those not so treated. More permanent cures have resulted when tuberculin has been used than where it has been omitted; many patients running a slow but steadily downhill course, in spite of open air treatment, improve and get well under tuberculin. Tuberculin has a favorable effect on the chronic toxæmia of tuberculosis, which disappears under its use to an astonishing degree. Cough and sputum frequently cease, or persist greatly lessened in amount. The conclusions the author draws are that tuberculin is the most valuable adjuvant to fresh air, rest, good food, we possess in the treatment of pulmonary tuberculosis. It is indicated in many types of cases, and in the hands of a competent administrator will do no harm. Reactions are often overlooked; they are not to be desired, and when frequent or violent are distinctly harmful to the patient. The dosage should at first be infinitesimal; increase should be very gradual. Time and tolerance bring success in the treatment by means of tuberculin. Tuberculin should never be used save in conjunction with strict hygienic and dietetic measures.

#### 5. The Treatment of Placenta Prævia.—

Crossen states that three points are to be kept in mind in the delivery of placenta prævia. 1, The dilation of the cervix must be gradual because of the danger of serious laceration; 2, there must be compression of the bleeding area during this gradual dilatation, to prevent dangerous hæmorrhage; 3, that method of delivery is to be chosen which gives the best chance of saving the fœtus, provided it does not unduly jeopardize the mother. The cervix should be dilated sufficiently to admit two fingers for more accurate examination. In many cases, particularly in multiparæ, this slight dilatation may be accomplished with the fingers, while in other cases a dilator will be needed. This procedure enables us to decide whether the case is one that will probably require only minor assistance in the process of delivery, or one that requires radical interference at once because of imminent danger to the mother. Delivery is a serious procedure in most of these cases and is accompanied with the danger of sudden fatal hæmorrhage. Consequently, the physician should take care to provide the required assistants, instruments, and materials to meet emergencies that may arise. Two assistants are advisable, one to attend to the anaesthesia and the other to assist the operator and attend to the intravenous administration of saline solution if necessary. If the patient is near a hospital she should be moved there. If the bleeding is not severe, or has been checked by firm packing, the removal to the hospital with the

patient perfectly quiet on a stretcher is less dangerous than an attempted delivery, with its possible serious emergencies, at the home.

6. Practical Value of Modern Conception of Syphilis.—Schalek says that, although it was always stated that one infection of syphilis conferred an absolute and permanent immunity, this was never accepted universally. But the few reports of reinfections could never be confirmed. It is known at present that there is a period during the existence of a chancre when multiple autoinoculations occur, and that, furthermore, there is a time limit to the protection conferred on an individual by his first attack of syphilis, after which reinfection may take place again. The diagnostic feature of one single initial lesion of syphilis, as distinguishing it from the multiplicity of chancroids, should not be relied on any more. Multiple syphilitic chancres have been reported lately by Taylor and others, appearing simultaneously or successively and in different stages of evolution. Finger's explanation of this recurrence seems most rational: Immunity begins and develops gradually with the first appearance of the primary lesion. It grows in intensity during the secondary stage, but never becomes absolute. After reaching its climax it again decreases in its potency until a virus which may have remained latent for a time can produce new pathological changes, or an infection from outside sources becomes a possibility.

7. Treatment of Eclampsia.—Moran observes that if, in spite of vigorous treatment, the volume of the urine is not increased, and the excretion of urea remains stationary or diminishes, together with persistence of menacing constitutional symptoms, it will be necessary, particularly if the fœtus is viable, to terminate the pregnancy. While the etiology of eclampsia is still unsolved, its clinical phenomena and pathology point to a probable intoxication of maternal, fetal, or combined origin. Therefore, sedation, elimination, and evacuation of the uterus are the chief indications in the treatment. The sedatives are valuable for their tranquilizing influence, while the delivery is being promoted or effected by other direct measures. The result in a given case will depend on the severity of the attack, the judgment and skill of the physician, and the rigid observance of asepsis. Essential to success is a well thought out plan of prompt but not over-zealous procedure based on the various phases of the disease, combined with a knowledge of the condition of the cervix and the changes which it must undergo before pregnancy can terminate or be terminated.

#### 9. The Eye Syndrome of Dementia Præcox.

—Tyson and Clark have examined the pupils in eighty-five cases. The result of their examinations is as follows: The findings indicate that dementia præcox is attended by such an ocular and ocular syndrome of alteration and loss, visual field, pupil and corneal sensitive as to materially aid in diagnosing this psychosis. Concentration of the syndrome will particularly aid in the distinctive diagnosis of dementia præcox from the manic depressive group, acquired neurasthenia, hysteria and the various forms of imbecility and constitutional inferiority. The syndrome is a potent corroborative

to the theory that dementia præcox is an autotoxic disease, and that the poison is primarily vascular, which finally induces neuronie degeneration. It points to a toxine of some sort, which is either a metabolic defect in the tissues (ductless gland defect) or, what seems more probable, that the poison is generated in the liver or in the gastrointestinal tract itself. The syndrome is of prognostic value, as the severer grades of eye changes are found in the more rapidly deteriorating cases. The optic nerve lesion is quite in accord with our best knowledge of the pathological anatomy of dementia præcox, in other tracts of the brain (than the optic nerve which itself may be counted an analogue). The early vascular changes in the brain ought to receive more serious investigation.

#### MEDICAL RECORD

May 2, 1908.

1. The Cancer Problem, By EUGENE COLEMAN SAVIDGE.
2. The Effects of Urban Congestion on Italian Women and Children. By ANTONIO STELLA.
3. The Fifth Nerve in Relation to Ophthalmic Conditions, By SAMUEL HORTON BROWN.
4. A Piece of Catheter Voided During Urination. By WALTER S. REYNOLDS.
5. The Inunction of Iodoform in Tuberculous Peritonitis, By SIDNEY F. WILCOX.

1. **The Cancer Problem.**—Savidge in his paper calls our attention to the fact that the yeast plant ferment was found to act on the left isomer, while the ferment of the mold acted upon the right solution. Elemental carbon exists as coal and as diamond. There is a difference between laboratory products and the substance derived from organic compounds, that is, the natural organic products rotate the polarized light either to the right or left, according to quality, but always one way, to the exclusion of the other isomer. There is a force that will cure some cancers and cause some cancers. The radial action of sun and ray is probably in the direction of a cure when it acts repressively on the noxious bacterial life. It is probably acting in the direction of heat when it destroys our assimilative and protective ferment. The author cites a case of a syphilitic who was attacked with smallpox. Recovery from smallpox left the patient permanently cured of his tertiary syphilis; the explanation was that the smallpox germ had killed the syphilis germ. When an item or an aggregate of items restores glandular activity, replaces the disturbed ferment protection, restores the isomeric integrity, that item thereby cures cancer. The author concludes in saying: A certain known, but not understood, "radial" force can act upon products containing the asymmetrical carbon atom to change their isomeric quality as shown by polarized light. That one force can so act presupposes that other forces may so act. The natural ferments contained in the secretions of the body, digestive and protective, "digest" one series of isomers and leave the opposite series untouched. Therefore, the action of this occult "radial" force—this assailing of isomeric integrity—can change protoplasm from digestibility to indigestibility to the natural ferments, and *vice versa*. The local cancer products consists presumably of changed isomers allowed to grow instead of being "digested." This is made all the more probable by the disappearance of the opsonic ferments in the

blood in all such diseases as have been subjected to controlled observation; and, specifically in cancer, by the gradual suppression of the enumerated ferments. These ferments—presumably—begin to modify long before transition from the preliminary to the final state called cancer. Therefore, even if there is no change in isomeric quality, the secretion suppression would explain the growth of the cancer weed cells that effective ferments would have removed. If there is no flaw in these significances, the cure for cancer, as well as its prevention, lies in the realm of synthetical medicine.

2. **The Effects of Urban Congestion on Italian Women and Children.**—Stella gives a great amount of statistical material, and concludes with the following words: Let us arrange for a better distribution of the immigrants not after they have reached Ellis Island, but before they decide to leave their motherland, by informing them of the wonderful resources of this vast continent, outside and beyond the large cities; let us educate them to the principles of hygiene and life, when they are settled here, and above all, let us distribute the work in appropriate areas outside of the city limits, so that proximity of the factory should not be as it is now, in a large percentage of the cases, the chief reason for their congesting the cities. Let us, finally, promote the building of model tenements at a low rent that will not absorb thirty-three per cent. of their income, and stimulate the philanthropy of the rich in this direction, and when we shall have given the people clean, healthy homes, full of light and sunshine, we shall have accomplished the physical and moral regeneration of the masses; we shall have given them that to which every human being is entitled, health and happiness.

1. Some Observations on Bronchitis and Emphysema, By SIR J. BARR.
2. The Physiological and Pathological Effects which Follow Exposure to Compressed Air (Arris and Gale Lectures), By MAJOR GREENWOOD, JR.
3. Primary Pneumococcic Peritonitis, By A. CUFF.
4. Observations on the Rectal Temperature after Muscular Exercise, By M. FLACK.
5. Calmette's Ophthalmoreaction, By T. H. BUTLER.
6. A Note on the So Called Stimulating Effect of Alcohol on Protoplasm, By W. H. KESTEREN.

1. **Bronchitis and Emphysema.**—Barr, after discussing the ætiology and pathology of bronchitis and emphysema, has the following to say as regards treatment. *Bronchitis.* The patient should be hardened and protected against the injurious influences of cold, dust, microorganisms, irritating gases, etc. He should live as far as possible in a pure, dry atmosphere which, at least during the acute stage of the disease, should be warm. Every person with a liability to bronchitis should forswear the use of alcohol in all its forms. It is one of the most frequent causes of chronic bronchitis and is never useful in treatment. When bronchitis is secondary to other diseases, the treatment is chiefly symptomatic. When it arises, as is frequently the case, from digestive disturbances, attention should be specially devoted to the stomach and bowels. As a rule the carbohydrates and fats should be cut down, a liberal allowance of nitrogenous food being granted. The

diet should not be too liquid, though a fair amount of hot water may be given. If there is any deficiency of lime salts in the blood, which is often the case when the expectoration is free and albuminous, a moderate amount of milk should be given, also gelatine. But where the expectoration is scanty and tough with bronchial spasm and râles, milk and gelatine should be avoided, the lime salts being in excess. Sodium chloride, which has a high osmotic equivalent, should be restricted. A good emetic is often an excellent preliminary treatment, and in all cases the bowels should be well cleared out with calomel or sodium sulphate. As a rule the fewer drugs used the better. Ammonium carbonate is certainly injurious in the early stages of the disease. Antimony and compound tincture of camphor with ipecac, are excellent remedies. If there is bronchial spasm and tough expectoration, decalcifying agents such as the citrates of potash and soda should be used, while on the other hand, where the expectoration is profuse and albuminous, calcium lactate should be given. In bronchial spasm the nitrites are very valuable, and potassium iodide is an important adjunct. When the acute stage has passed, tonics such as strychnine and quinine should be given. Counterirritation is often extremely valuable, the writer preferring mustard poultices. *Emphysema.* What has been said of bronchitis applies largely to emphysema: The treatment should be chiefly dietetic and hygienic, and prevention is always better than cure. The patient's appetite is frequently too good, he is stout and plethoric, and thus there is a demand for more oxygen than the lungs can supply. Moreover the plethoric and cyanotic conditions lead to congestion of the lungs, greater respiratory efforts are made, and the emphysema is increased. The patient should be starved as much as possible. This is usually difficult, but at any rate the fats and carbohydrates should be diminished. The thin, spare patient does best. Too much table salt should be prohibited, but plenty of fruit and a fair amount of green vegetables can be allowed. The patient should live in a dry, warm atmosphere, and should practice respiratory gymnastics, being taught how to expire rather than inspire. Comparatively few drugs are of any value, the most generally useful being the iodides. Thyroid extract may be added if there is any deficiency in metabolism. If there is much cough, opium must be used.

3. **Pneumococcic Peritonitis.**—Cuff states that it has been established beyond all doubt that cases of peritonitis occur in which most careful search, both ante and post mortem, fails to show any primary lesion in any abdominal viscus. The cause of many such cases is the pneumococcus. Pneumococcic peritonitis is at all times uncommon. It is most often met with in children, being extremely rare in adults. It may be diffuse or localized in the form of an intraperitoneal abscess. Onset is sudden with severe pain, the previous health having usually been good. The course of the disease is very rapid: free fluid in the abdominal cavity is an early sign. The pus is peculiar in that it always contains a large quantity of coagulated lymph like curdled milk. The writer reports a series of five cases from which he draws the following conclusions:—

1. That an acute diffuse or localized peritonitis may be the sole symptom of a pneumococcic infection. 2. Such cases possibly form a considerable proportion of those anomalous cases of peritonitis without visible lesions of any of the abdominal viscera. 3. Their sudden onset after previous freedom from abdominal trouble, together with the frequent accompaniment of diarrhoea, and signs of early systemic poisoning, may perhaps serve to assist in differentiating them from peritonitis caused by other infection. 4. They may be followed by pneumococcic lesions in other organs of the body. 5. Their prognosis is extremely grave.

5. **Calmette's Reaction.**—Butler has carefully investigated the so called ophthalmoreaction for tuberculosis as introduced by Calmette. He concludes that it is a safe and simple practical test that can be used by the general practitioner, and that it does not inconvenience the patient. It is a very useful aid to diagnosis, but occasionally the results are equivocal. The patient's eyes must be carefully examined and the condition noted in a book. It is essential that there be no preexisting conjunctivitis, for the reaction would then be masked. One or two drops of the solution must be instilled into the lower cul-de-sac and the eye held open for a few seconds. If the subject is tuberculous the eye will begin to redden in about three hours, and lachrimation will be complained of. At about the sixth hour the caruncle begins to swell, and there may be a slight fibrous exudation which gathers in filaments in the lower conjunctival sac. The reaction reaches its maximum in from six to thirteen hours; there is no rise in temperature and no general malaise. The inflammation may vary in degree from slight lachrimation and an almost imperceptible enlargement of the caruncle to a severe conjunctivitis which may last for several days or even for weeks. But there is little danger to the eye unless it be affected with tuberculous disease—a rare condition. The intensity of the reaction bears no relationship whatever to the severity of the tuberculous process. Every case of obvious tuberculosis tested by the writer gave the reaction, and only one slight reaction was observed in an apparently healthy individual.

- 6. Another Description of the Sacred Tails of the Clay-fish. Treatment by Fracture of the Clavicles with Good Results. By F. H. MURPHY.

1. **Fractures of the Long Bones.** Thompson in the first of his Hunterian lectures, discusses fractures of the neck of the thigh bone, dealing especially with the anatomy of the bone itself. In the ends of the bones of an ordinary adult man there

are developed definite lamellæ running in the main direction along which pressure is transmitted. Certain other lamellæ are also developed, gradually crossing these pressure lamellæ at right angles. These are known as tension lamellæ. Their presence generally increases the elasticity and therefore the strength of the bone. In the young person, as well as in the old, these pressure lamellæ are not well seen, nor are the tension lamellæ. In the young person the cancellous tissue at the ends of the long bones is so dense and the meshes are so fine that the pressure and tension lamellæ can hardly be demonstrated. In the old person the bone fibres are so obscured by the presence of fat that they are very difficult to discover. Relatively large masses of fat develop in the part of the bone which is least subject to pressure. Fractures of the neck of the thigh bone have perfectly definite causes, the statement of which depends to a large extent upon the knowledge of the internal structure of the upper end of the femur. Now, in addition to the two series of lamellæ, there is a third series, which pass from the upper surface of the head to the lower surface of the neck, and thus to the compact layer on the inner surface of the shaft of the femur. This layer or spur of bone is known as the calcar femorale, or Merkel's or Adam's arc, is a nearly vertical ledge of compact bone. It does not always disappear in old age, but, on the other hand, it is not invariably present, even in young people. The calcar in extracapsular fracture of the neck of the femur is responsible for the edge and lower end of the clusel, whose other parts are represented by the head and neck of the femur. The calcar certainly produces the vertical secondary fracture of the great trochanter and upper part of the shaft of the femur, and may be held partially responsible for the horizontal secondary fracture near the base of the great trochanter. In intracapsular fracture of the neck of the femur the pressure starts from the front of the upper part of the neck. If the patient is in the flexed position when the accident happens, the ligamentum teres is not strong enough to resist the sudden force which is put upon it, and so it may be either stretched or ruptured. The anterior surface of the neck of the femur then comes into forcible contact with the corresponding part of the acetabulum, and the fracture is begun. The line of fracture then passes for some distance in a transverse direction along the neck until it meets with the lamellæ coming down from the anterior upper surface of the head of the femur to the posterior and under surface of the neck of the same bone, and is by them deflected so as to form either a posterior or an inferior tongue of bone.

4. **Epidemiology of Diphtheria.**—Sambon calls attention to the widespread prevalence among animals of diphtheria, or, at any rate, of a disease resembling diphtheria, and caused by microorganisms apparently morphologically identical with the Klebs-Löffler bacillus. That diphtheria may be conveyed from the lower animals to man, and vice versa, is a very old and general belief. The simultaneous occurrence of diphtheria epidemics in man and of epizootics of a similar nature in animals has been observed again and again in all ages and places. Human diphtheria bacilli inoculated into

susceptible animals produce the disease, and our position is very much the same as in tuberculosis, where two forms of tubercle bacilli (the human and the bovine) are recognized. And it is generally held that bovine tuberculosis can be and is transmitted to man, and human tuberculosis to animals. The writer holds that the conveyance of diphtheria by means of milk and eggs would explain the great frequency of the disease in young children, because their food consists almost entirely of these two articles given raw or almost raw. It is probably by means of these foodstuffs that the disease is brought into towns, although, of course, it may also be introduced by infected human subjects or by infected animals, especially birds, such as pigeons and sparrows. The pigeon is quite common in the parks and squares of large cities, and it is quite conceivable that horses and sparrows contract the disease from them. The cat, a natural enemy of the sparrow, may contract diphtheria from that bird, which is likely to fall an easy prey when paralyzed by the disease. The rôle of the cat in connection with diphtheria is of great importance. This animal, after prowling in field and gutter, has access to the bedroom and sleeps on the bed with and is fondled by the children. Cats have been noticed to suffer simultaneously with man in almost every outbreak of diphtheria. But in diphtheria, as in plague, one particular kind of animal seems especially concerned in the wider spread of the disease. In plague the rat, owing to its wide distribution, its great numerical prevalence, its close association with man, and, above all, its migratorial habits, is the true cause of the great pandemics which at various intervals desolate the world. In diphtheria probably a similar rôle is played by the pigeon.

#### BERLINER KLINISCHE WOCHENSCHRIFT

March 30, 1908.

1. The Symptomatology and Treatment of Tumors of the Cerebellum, By E. SIEMERLING.
2. Concerning the Practical Importance of Opsonins, By JÜRGENS.
3. The Efficiency of Pepsin and a Simple Method for Its Estimation, By OSKAR GROSS.
4. The Action of the X Rays upon Ferments, By P. F. RICHTER and GERHARTZ.
5. Operative Treatment of Diffuse Purulent Peritonitis, By KOTZENBERG.
6. Contributions to the Surgery of the Brain and Spinal Cord (*Continued*), By HERMANN KÜTTNER.
7. Insects and Ticks as Disease Carriers to Men and Animals, By MOELLERS.

2. **Practical Importance of Opsonins.**—Jürgens considers that the opsonic index must not be relied on too much, but that when it is used carefully and critically in the clinicopathological syndrome it can give the observer a great deal of help.

4. **Action of the X Rays on Ferments.**—Richter and Gerhartz have instituted a number of experiments the results of which go to show that the ferments are affected in no way by the x rays. Some writers have ascribed an excitant, others a restrictive action on ferments to the x rays, but these would seem to be erroneous observations, or at least to rest on very insecure foundations.

5. **Operative Treatment of Diffuse Purulent Peritonitis.**—Kotzenberg includes under diffuse peritonitis only that form in which pus is present

throughout the entire abdomen, the serous covering of the intestine exhibits evident signs of peritonitis, and there are large accumulations of pus not only in the pelvis but also below the liver and the spleen. He considers that the principal points of the rational treatment of such a condition are drainage by means of the tampon drainage of Dreesmann, restoration of the intraabdominal tension by accurate suturing of the abdominal walls in three layers, leaving an opening exactly large enough for the glass drain in the lower angle of the wound, thorough irrigation of the abdominal cavity with salt solution of the proper temperature, which is not removed but allowed to remain in the cavity, and the maintenance of the patient in an oblique position. Particular care must be exercised in the renewal of the tampons in the glass drain.

6. **Contributions to the Surgery of the Brain and Spinal Cord.**—Küttner in this number gives the details of four cases. One of myelitis and myositis ossificans after measles, one of successful removal of a round cell sarcoma from the left frontal lobe, one of extirpation of a round cell sarcoma from the anterior central convolution followed by death, and an exploratory operation for a tumor of the brain which was not found.

3. On Adenoma of the Liver. By O. D'ALLOCCO.
4. On a Case of Anencephalus Caused by Dystocia. By A. BUSSI.

1. **Experimental Typhoid in Goats.**—Gabbi studied typhoid infection experimentally in goats, and reports his results in a preliminary communication. It has been known for some time that the milk of tuberculous cows is capable of carrying tuberculosis to human beings, especially to children. Malta fever is now known to be transmitted through the milk of goats. Researches carried on by the author and his pupils in Sicily and Calabria have shown that not only Maltese goats, but also goats from the regions mentioned carry Malta fever germs, and transmit the disease through their milk without showing any revealing sign which would enable one to distinguish these goats clinically from uninfected animals. The author furthermore noted within the last three or four years that there were many more typhoid patients admitted to the clinic than patients with Malta fever, and it occurred to him that, possibly, the milk of goats may transmit typhoid infection. Fiorentino, a pupil of Gabbi, who was looking for Malta fever in goats, found, in the course of his investigation, that there was a typhoid epidemic in a locality in which six per cent. of the goats were found infected with typhoid. He therefore believes that the milk of goats may be a possible carrier of typhoid infection, and in order to determine this he proposed to find out whether goats are really susceptible to infection with the typhoid bacillus, whether in these mammals experimental infection may be transmitted through the milk, and if so, whether the milk of goats may carry the disease to human beings. The results of the in-

vestigations thus far indicated that the injection of virulent typhoid bacilli in goats produced a brief rise of temperature, and that these bacilli were eliminated through the milk of the animal for several days after the fever had disappeared. The Widal reaction was present in the goats, and could be found on several days after the disappearance of the fever. The goat, as in the case of Malta fever, seems to remain indifferent, practically, to the typhoid infection which passes through it. The milk of these infected goats showed no change save the presence of the bacilli.

1. A Case of Acute Aortic Insufficiency of Traumatic Origin. By UMBERTO DEGANELLO.
2. Contribution to the Study of the Pathogenesis of Cystic Kidneys (*To be continued*). By DOMENICO TADDEI.
3. The Filtrability of Human Vaccine Virus. By ODDO CASAGRANDE.

1. **Traumatic Insufficiency of the Aorta.**—The case reported by Deganello was that of a man, aged thirty-five, driver, who had been well until the day of the accident, which consisted in a severe crushing injury of the thorax, especially of the præcordial region. After the accident there were severe cardiac symptoms for a time, but the patient lived, and a month later presented the evident signs of a cardiac lesion. There was dyspnea, cyanosis, signs of pulmonary congestion, slight palpitation, etc. On examination there were found a noteworthy hypertrophy of the left ventricle and an intense diastolic murmur, which had a musical quality and was heard especially over the aortic region. The pulse was bounding. The symptoms of loss of compensation went on progressively and rapidly, and the patient died five months after the accident. At the autopsy it was found that the two anterior aortic valves were torn for a certain distance from their line of insertion, so that they did not close completely. There was also a dilatation of all the cardiac cavities, especially of the left ventricle, which was also hypertrophic. On histological examination of the valve it was found that some new connective tissue had formed in it in an attempt to heal the laceration. The author urges the necessity of microscopical examination in such cases, as only by this means can we prove the traumatic origin of the lesion.

## ROUSSKY VRATCH

5. Blood Examination in Surgical Diagnosis. A Practical Study of Its Scope and Technique (*Continued*), By IRA S. WILE.
6. A Case of Stricture of the Esophagus Treated by Gastrostomy and Retrograde Dilatation by Ochsner's Method, By F. W. PARHAM.
7. Report of a Case of Ununited Fracture of the Shaft of the Humerus and Paralysis of the Musculospiral Nerve, By DUNCAN EVE.

1. **Abdominal Tenderness.**—Witherspoon remarks that the location of tenderness undoubtedly is a most valuable aid in arriving at a diagnosis. It is a fact that a viscus usually lies directly under that part of the abdominal wall which is innervated by somatic nerve fibres coming off from the same spinal segment as the nerve fibres which supply the viscus. This is due to developmental shifting, in like degree, of the splanchnic and somatic structures. It may, therefore, be argued by one, that the tenderness is located in the viscus, and by another that it is in the parietes. The location, nevertheless, bears an important relation to the viscus involved regardless of the actual seat of tenderness. One of five general conditions may be signified by abdominal tenderness: 1, a lesion of an abdominal viscus; 2, a lesion of the wall; 3, a lesion of a viscus outside of the abdomen awakening tenderness in the abdominal wall; 4, a central nervous lesion or one which implicates nerve trunks supplying the abdominal wall; and 5, a systematic disorder accompanied by abdominal pain and tenderness. The degree of sensibility of different individuals varies greatly in the normal. One remains practically comfortable under rough handling, while another objects to the mildest pressure. It is always well to note the general sensibility of a patient before proceeding to obtain evidence of a local increase of sensibility. It has probably happened time and again that the first touch of the examiner has called forth an expression of discomfort and led to a premature announcement of "appendicitis," "gallstone disease," or "pelvic inflammation." In commencing to palpate always begin upon an area least suspected of harboring disease. This gives an idea of the normal response; moreover, the patient is placed off guard and when the tender area is approached the muscles are not fixed guarding against pain.

#### 4. Postoperative Treatment of Adenoid Pa-

tients.—Sheedy emphasizes the following points in postoperative treatment of adenoid patients: 1. Keep children in bed for from two to three days after operation, and away from other children. 2. Keep parts clean by use of alkaline washes and medicated mentholated oil solution. 3. Use constitutional and reconstructive medication. 4. See that thoracic gymnastics are practised for a long period. 5. Zinc oxide plaster over the mouth at night to keep the mouth closed until normal breathing is established. 6. Watch for return of the growths.

#### THE JOURNAL OF NERVOUS AND MENTAL DISEASE

April, 1908.

1. Hysteria in Children, By JOHN JENKS THOMAS.
2. A Contribution to the Pathogenesis of Some Epilepsies. A Preliminary Contribution, By SMITH ELY JELLIFFE.

2. **A Contribution to the Pathogenesis of Some Epilepsies.**—Jelliffe remarks that it is practically conceded that there is more than one epilepsy. Clinically we recognize the classical forms of grand mal, petit mal, psychical equivalents, etc.; forms that dement rapidly, which are in marked contrast with those that do not. Pathologically a multiplicity of alterations have been described, all tending to show that different processes are active. Etiologically a similar variability of factors is observable. There are the epilepsies following an acute poison of some nature; usually the toxine of an acute infectious disease. The epilepsies so prone to follow scarlet fever, measles, diphtheria, whooping cough, streptococcus infections, and influenza offer the most striking examples. While it is yet uncertain what are the affinities or perhaps lack of affinities of the poisons of these differing infectious diseases, and their relation to other poisons, it has been amply demonstrated by a number of workers in pathology that alterations in the character of the blood and changes in the walls of the bloodvessels throughout the body are very characteristic, and it is not a far cry to apply the knowledge of such study on vascular alterations to such changes in the brain. Minute hæmorrhages, capillary thrombi from agglutination, endothelial alterations are the precursors of the more extensive and permanent glia alterations, made necessary by the general phagocytic activity of these connective tissue elements. Having had under observation a striking example of poisoning by santonin in a young child, with the production of a permanent epileptic state, Jelliffe made some experimental studies with this substance, in order to gain some information concerning its action on the cortex of lower animals. He concludes that following santonin poisoning there results a definite cellular alteration in the ganglionic areas of the psychomotor area, with death and destruction. This accounts for the profound functional disturbances resembling epileptiform convulsions. That as a result of chronic poisoning by the same substance a definite form of neuronophagia is demonstrated, which by inference from the many studies bearing on this subject, may be interpreted as a forerunner of a glial infiltration. Whether this latter will be found in his specimens the author cannot yet say. Should such be the result, it would afford excellent evidence for a more definite understanding of the cellular mechanisms which lead to the gliosis of many chronic epilepsies.

## Proceedings of Societies.

### MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

*Special Meeting, Held on February 3, 1908, at the Staten Island Academy, St. George, Borough of Richmond.*

Dr HENRY C. JOHNSTON in the Chair.

(Concluded from page 871.)

The diagnosis having been made, the most important point in the treatment was rest. The securing of this, he said, would depend upon the part affected, on the means at hand, and partly on the skill of the surgeon in the use of different forms of treatment. If the upper extremity was involved, a plaster of Paris splint taking in the joint on each side of the affected one would probably be the most efficient device. In disease of the spine the great majority of patients did better if allowed to go about, but if an abscess was forming, the temperature running high, the deformity increasing, or paralysis beginning, the patient should be kept quiet and not allowed to stand. In such cases the wire cuirass, with a head support to exert traction on the spine in its long axis, was the most suitable appliance. This must be so shaped as to exert a corrective influence on the curvature, if one was present, and, if the disease was in the upper dorsal region, an apparatus such as Whitman's shoulder support should be employed to avoid the forward reaching of the shoulders which tended to curve the spine. In the cuirass the patient could be carried out of doors and receive the benefits of fresh air, sunshine, and diversion. This method of treatment was especially available in young children. For ambulatory cases the plaster of Paris jacket (with a jury mast if the disease was high seated) or the Taylor posterior support was applicable.

In disease situated in the lower extremity a splint combining traction with fixation was superior, according to Dr. Sayre's experience, to either the plaster of Paris splint or the Thomas splints for knee and hip. The removal of weight bearing was essential, and the particular method employed to give rest to the inflamed joint was not of much importance, provided it actually did afford rest, and not a pretense of it, as was often the case when a loose and short envelope of plaster of Paris was put around the knee, and the patient allowed to walk about.

The second principle in combatting bone tuberculosis was to increase the vitality of the patient as much as possible. Fresh air and sunshine were vital, and one of the most powerful arguments in favor of treatment by apparatus, as opposed to bed treatment, was the opportunity which this afforded for these essentials while the patient was wholly or partially ambulatory. Caged animals were prone to be affected with tuberculosis, and the same was true of caged human beings. While the necessity of fresh air in abundant amount had long been recognized in pulmonary tuberculosis, in tuberculosis of the bone this had not been insisted upon as it should have been until very lately. Fresh air, not merely for one or two hours a day, but for the whole twenty-four, was the proper quantity, and to secure this it was not always necessary for the patient to go to a country resort.

Opening the windows was one way to get fresh air; yet most persons seemed to think that in order to obtain it one must go out of doors. Many maintained that it was essential that the air should be cold, but the speaker believed that its temperature was not of special importance, and that excessive cold was quite unnecessary. As sunlight was essential, as well as fresh air, the patient, if he could not go out or be placed in the open air, should occupy a room with a southern exposure. Feeding was another essential, and, as the appetite was often capricious in these cases, five or six meals a day might be required in order that the proper amount of nourishment should be received. As both the appetite and digestion were greatly improved by diversion of the mind, this was a point which should always receive attention. Overfeeding, however, was to be guarded against, and a dose of calomel might be required from time to time to clean out the alimentary canal. Many observers believed that by the long continued use of guaiacol or guaiacol carbonate the fermentation processes so often seen in the digestion of tuberculous patients were lessened, and the nutrition thereby improved.

In addition to these well recognized methods of raising the vital resistance, it had been suggested that the patients should be treated with an antibacterial serum, and for this purpose the new tuberculin (T. R.) of Koch and the Marmoreck serum had been employed. At the present time, however, our knowledge of the possibilities of this treatment was extremely small. A number of observers had reported certain effects, but they had not been convincing, and up to the present time the results of serum injection in bone tuberculosis were of more academic interest than practical utility.

The treatment of the abscesses which occurred in a large percentage of cases was most important, and one measure which the speaker had found of great value in properly selected cases was the use of the actual cautery. Before opening one of these tuberculous abscesses it should be borne in mind that in the vast majority of instances such an abscess led up to a sequestrum somewhere in the bone, and that it might be extremely difficult to follow it to its source and thoroughly remove all the diseased tissue. Unless this could be done the door would be laid open for the infection which it was so important to prevent. If the abscess did not interfere with the application of an appropriate brace, it was better not to interfere with it, certainly early in its history. Later on, these collections of tuberculous matter seemed to wall themselves off from the bone where they originated, and in such old abscesses, or at an earlier period if the abscess showed a tendency to become infected, it might be wise to evacuate it through a small incision. Care should be taken to injure the abscess wall as little as possible, and after a thorough washing out with sterile normal salt solution the incision should be closed without drainage. In some instances this incision would heal, but in others it would break down later on, and as subsequent dressings very careful attention would be required to prevent the tract from becoming infected. In the majority of cases the cavity left by the removal of carious bone or a sequestrum, if thoroughly cleansed, had better be left to fill with blood. In it

was clean, new bone would soon be organized, and supplant the blood clot, while, if it was not clean, suppuration would follow. It was advisable to avoid resection of tuberculous joints, if possible, but in exceptional instances (as where the circumstances of the patient rendered it impossible for him to submit to a prolonged course of treatment—lasting perhaps two years) this became necessary, and recovery took place with a stiff joint. In speaking of the local hyperæmia treatment of Bier, designed to improve the nutrition of the part, Dr. Sayre said that the time required for treatment did not seem to be shortened by this procedure. If it was resorted to, he thought that in connection with it proper mechanical support should be employed. The whole aim in the treatment of bone tuberculosis was to cut the disease as short, and to cause as little destruction of tissue, as possible.

—  
*Meeting of February 17, 1908.*

The President, Dr. THOMAS E. SATTERTHWAITE, in the Chair.

**The Late Dr. Loomis.**—The committee on the death of Dr. H. P. Loomis (Charles H. Knight, M. D., chairman) reported as follows:

The Medical Association of the Greater City of New York is called upon to record, with deep regret, the loss of one of its early members and a frequent contributor to its proceedings, Henry Patterson Loomis, who died at his home in this city on December 22, 1907. He was born in New York in 1858, the son of a father well and widely known as a medical author, practitioner, and consultant. He inherited many qualities of mind and heart which endeared him to his friends and enabled him to achieve distinction in his profession. He was graduated from Princeton University in 1880, and took his medical degree at the Medical Department of the University of the City of New York in 1883. He was an attending physician at Bellevue Hospital and until recently at the New York Hospital. For several years he held a professorship at the University Medical College, and at the time of his death was professor of materia medica, therapeutics, and clinical medicine at Cornell University Medical College. He was a facile writer, a successful clinician, and an apt teacher. His death in the prime of life, and with many years of usefulness before him, is a source of profound sorrow to a wide circle.

**The Death of Dr. R. W. Taylor.**—The committee on the death of Dr. Robert W. Taylor (Edward B. Bronson, M. D., chairman) presented an elaborate report, which was in part as follows:

It is wholly fitting that a halt should be called in our proceedings to do reverence to the memory of one of the most distinguished of our members. To us was rendered what was probably his last public service in that domain of medicine in which his life work was mainly engaged. Even then, hampered as he doubtless was, and with something of his old time vigor abated, through the encroachments of the fatal malady to which he shortly after so suddenly succumbed, there was still in evidence that sincerity of purpose, zeal, and earnestness which had always characterized the spirit of his work.

Though chiefly preeminent in the field of that most intricate and absorbing of all the enigmas of medical research, syphilis, Taylor's name was also famous for signal services looking to the relief of those other ills of erring flesh—the hideous progeny of lust and folly. Through the welter of these afflictions of humanity, involving, as they do, the innocent as well as the erring, he waged a lifelong combat; seeking the roots and remedies of evil, and bearing aloft the torch of hope. Nor did these Augean labors limit the range of his activities. Beginning at a time when more than now were associated in a common specialty both venereal diseases and the general affections of the skin, his interest in and contributions to dermatology were most valuable, and occupied him to the end. The list of his published works in these fields of research is an extensive one. They have had great influence in the medical world, and a considerable number of them were translated and published in foreign tongues.

Beside his literary labors should be placed his long service at Charity (now the City) Hospital, where he trod in the footsteps of those earlier masters, Van Buren and Bumstead, together with his public teachings as professor in the chair of either venereal or skin diseases, first at the Woman's Medical College, later at the College of Physicians and Surgeons and also at the University of Vermont. In all of these labors his work was indefatigable, thorough, and conscientious. With a catholic spirit he combined the temper of the conservative.

But, while acknowledging the intellectual achievements, let us not forget the amiable qualities of the man. By nature impetuous, while sometimes hasty of speech and on occasion resentful of real or fancied injuries, Taylor was a loyal friend and an agreeable man to meet. In his manner, with its air of cordiality, cheeriness, and bonhomie, there was a something that savored of a personal compliment. He liked to be liked, as in his home life he loved to be loved. The pity of it is that in his home, where all should have been happiness and content, one deep shadow of affliction succeeded another, till in his latter days lonely grief tinged his life with sombreness and doubtless accelerated its end. So, in our acclaim over the triumphs of an accomplished career, a successful life, there intrudes the note of pathos, an undertone of sympathetic regret. Peace be to his ashes! Lasting honor to his shade!

**Resolution on the Retirement of Dr. Satterthwaite.**—The following preamble and resolution, presented by the recording secretary, Dr. P. Brynberg Porter, were adopted:

The Medical Association of the Greater City of New York desires to record its high appreciation of the services rendered the society during the past four years by Dr. Thomas E. Satterthwaite, now retiring from the presidency. Dr. Satterthwaite has by his self sacrificing and unremitting labors placed this association on a level of scientific achievement which it had not previously attained. He has successfully carried out the plan of presenting in turn the latest research and practical work in all the various departments of medicine and surgery, and this has been done by the ablest exponents of the subjects treated of, not only in the different boroughs of New York, but in Philadelphia, Washing-

ton, Baltimore, Boston, Albany, Buffalo, and other cities. So admirably has the high aim sought been accomplished that the programmes of our monthly meetings have excited unusual attention and have been universally admitted to be of a scientific excellence and value seldom reached. In many other ways also has Dr. Satterthwaite worked faithfully for the interests of the association, while he has won the affection and esteem of all its fellows by his geniality and urbanity and by the dignity and courtliness with which he has presided.

*Resolved*, That the Medical Association of the Greater City of New York tender to Dr. Satterthwaite its sincere thanks for all the noble work he has done in its behalf, and express to him its profound regret at his retirement, together with its heartfelt wishes for his future welfare and happiness.

#### The Opportunities of a Great Medical Society.

—On retiring from the presidency of the association, Dr. THOMAS E. SATTERTHWAITE made an address on this subject. There were, he said, four large medical bodies in New York: the Academy of Medicine, the New York and Kings County societies, and this association. Each of these assumed certain functions, duties, and responsibilities which were their distinguishing features. After all, however, there were, he thought, some general principles which underlay all other considerations, governing the activities of such organizations. Along what lines, then, and in what manner was progress to be most profitably made? From the programme of the meeting of a county society in Kentucky which he had recently seen it would seem that there was a movement in that locality to have some sort of postgraduate course for the members, with weekly meetings devoted to the consideration of special subjects. This Kentucky society was undertaking a campaign of education, and the plan might well serve as an example for other large general societies. Supposing, however, that another course were pursued, and that a society would, for instance, undertake to "regulate the practice of medicine and surgery," holding out that among its prime objects were the prosecution of unlicensed or criminal practitioners, unregistered midwives, and medical impostors in general; it might always be reasonably objected that the crusade, though laudable in theory, and also in practice if carried on with discretion and good faith, would still be open to the imputation that so called regulation did not invariably regulate. Perhaps, too, some one might be bold enough to ask within what limits the society was proposing to exercise legal functions. Certainly most members of these large societies, if the choice were offered them, would be apt to favor more medicine and less law in their programmes.

For we must, first of all, in some way, keep abreast of the advances in the various departments of medicine and surgery, if we are to practice with safety to our patients and satisfaction to ourselves. No one of us had either the time or the ability to cope successfully with even the chief problems which confronted us, and it would seem as if our larger medical bodies, representing as they do every phase of our art, might easily be the most important factors in disseminating this very im-

portant knowledge, and that in the most palatable and digested form. Who that valued his time would not prefer to spend two hours in hearing some vexed question threshed out by experts, rather than to be forced to listen to a one sided presentation of an unimportant topic, the exploitation of immature ideas, or collections of ill assorted parts? Four years ago this society, through its council, undertook a campaign of education, and had kept it up year by year, only halting its scheme when the general public was looking for special information on such live questions as pure milk, water supplies, disposal of sewage, and the like, or when the opportunity was particularly favorable for discussing more theoretical questions, such as nutrition, immunity, pathogenic protozoa, etc., in which the medical profession in general was always profoundly interested. More than this, who would not believe that opportune discussions on such public questions as those mentioned were instrumental in shaping useful legislation, and that this society did effective work thereby for the city, State, and nation perhaps?

Except for these occasional variations, the year had been divided in such a way that the entire fields of medicine and surgery had been systematically touched upon at their most important points; more time, of course, being devoted to general medicine and surgery, and less, proportionately, to the smaller specialties. For each session the best obtainable expert talent was secured, whether in New York or other cities. As indicative of the efforts made to secure the services of the best men during these four years, more than fifty nonmembers had been invited to contribute to the programmes, and they had represented a geographical area extending from Montreal to Savannah and from Boston to Buffalo. This statement also illustrated the fact (constantly becoming more evident) that many topics important for medical men to be acquainted with could not be discussed advantageously without the help of laymen, such as the chemist, the pharmacist, and the civil engineer. Fortunately, the larger societies operating on this basis attracted representative audiences, so that the lay specialist had an incentive to appear before them, particularly as reports of the meetings were published in the prominent medical journals. Under these circumstances also our general societies should be more attractive to every kind of specialist than they were at present, since meetings such as those described necessarily enlarged his field of view, which otherwise tended to gradually become smaller and smaller. Medicine was both an art and a science. It had abandoned the realm of magic and mysticism, and was amenable to the same general laws as governed in the world of physics. It required the same sort of apparatus, the same kind of reagents, and the same mental attitude and training which are essential to the physicist.

In speaking of the importance of the social element in a large society, Dr. Satterthwaite said that, with some, friendly greetings stood for more than the scientific programme; but whichever were placed first in one's estimation, there was nothing but good to be had from a kindly word and a hearty grasp of the hand. This social side of the association's meetings had been especially emphasized in

the two extra borough meetings recently held, where the attendance was small enough to give each member the opportunity to meet and greet his fellows cordially, and yet large enough to encourage the speakers to do good work. The large societies ought also to provide some practical protection for their members in the legitimate and proper discharge of their professional duties. In closing, he said that the association would have a president possessing all the qualifications necessary for maintaining a high standard of achievement, a membership representative of the best medical men in the city, and, lastly, a sufficient balance in the treasury. He would venture the hope that the campaign of education inaugurated by it would continue to be a dominating feature, and that its teachings would always be sound and its policies wisely aggressive.

(To be concluded.)

### Letters to the Editors.

#### THE PALLIATIVE TREATMENT OF PROSTATIC HYPERTROPHY.

126 EAST THIRTY-FOURTH STREET,  
NEW YORK, April 22, 1908.

To the Editors:

Having read the most valuable article of Dr. Frederic Bierhoff under this title, in your issue for April 18th, I wish to be permitted to say a word about the author's erroneous interpretation of the term "palliative" in the sense of "nonoperative." The more I admire Dr. Bierhoff's writings, the more I regret that such a distinguished author should repeat an error made by others before him.

*Pallium* is a Latin word, and means a covering garment, a cloak; it was the Greek outer garment in distinction from the Roman toga. The *pallium* was given by the Roman emperors (from the fourth century) to the higher bishops. *Pallium caritatis* is the cloak of Christian love. *Palliatio* is new Latin, and means covering with a cloak in the meaning which we figuratively express by the word "whitewashing." Palliative, from the Latin *palliatius*, a, um, means covered with a cloak; in medicine a palliativum, or palliative remedy or treatment, is a remedy or treatment which is employed to ameliorate symptoms, to do for a while until a radical remedy (not necessarily an operation) can be applied or in case a radical cure is out of the question. A palliative cure is the opposite of a radical cure; that is, palliative treatment is directed against the symptoms only (not against the disease itself). *Eo ipso*, even a surgical operation may under certain circumstances be nothing more than a palliative measure. A. ROSE.

#### ANCIENT PHTHISIO THERAPY.

1022 NORTH FIFTH STREET,  
PHILADELPHIA, April 30, 1908.

To the Editors:

In connection with an article entitled A Retrospect in Phtthisiotherapy, by Henry Farnum Stoll, M. D., in the *Journal* of April 18th, I would say that Pliny, in a letter to his friend Valerius Paulius (Book V, Letter 19, Orey's Translation), stated that he was going to send to his (Valerius Paulinus's) estate his freedman Zosimus, who was evidently suffering with pulmonary tuberculosis.

In the letter he says: "It is now some years since he was pronouncing a speech with great vehemence and earnestness, when he spit blood, and, upon that account, being sent by me into Egypt, after a long stay in that country, he returned lately in a confirmed state of health; since which, as he has exercised his voice for many days together, he was threatened with his old infirmity by a little cough and afterward again spit blood. For which reason I determined to send him to your estate in Forojulium, having often heard you say that the air there was healthy, and the milk particularly prevalent in curing disorders of this kind."

From this it is evident that in the early days of the Roman Empire there were some who believed that climate and milk were useful in the treatment of phthisis, and, moreover, it proves the truth of the saying, "There is nothing new under the sun."

J. F. E. COLGAN.

### Book Notices.

[We publish full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we review those in which we think our readers are likely to be interested.]

*Vitality, Fasting and Nutrition.* A Physiological Study of the Curative Power of Fasting, Together with a New Theory of the Relation of Food to Human Vitality. By HEReward CARRINGTON, Member of the Council of the American Institute for Scientific Research, etc. With an Introduction by A. RABAGLIATI, M. A., M. D., F. R. C. S., Hon. Gynaecologist and Late Senior House Surgeon, Bradford Royal Infirmary, etc. New York: Rebman Company, 1908. Pp. 648. (Price, \$5.)

The author as a result of much reading, and fortified by many quotations, endeavors "to show that what little the medical profession is supposed to know of the nature of disease is totally wrong; that their theories of the origin and nature of disease are erroneous *ab initio*; and that every new discovery made, which they have considered an unmixed blessing and a sign of progress, has, in reality, only led them further and further from the truth, and away from an understanding of the real cause and cure of disease." He asserts that there are only two schools of healing in the world, the hygienic and any other, which includes all others. We are left somewhat at a loss as to what a hygienist is, but his attitude toward disease is defined from a book by Emmet Densmore, who regards it as a "curative action on the part of the ruling (vital) force." The author informs us that no one part of the body can possibly be affected without all other parts being also involved, and we strive to grasp the idea that all talk of local diseases is "non-sense pure and simple, and implies either ignorance or shortsightedness on the part of any man who uses the term as to what constitutes the real nature or essence of disease."

The author asserts that he takes "the broad stand, and defends the philosophic principle," that the supposed action of drugs on certain tissues, organs, or localities is altogether mythical and does not exist in reality, and if proof is wanted you are advised to study the philosophicomical writings of a Dr. Trall, author of *Water Cure for the Million*, which was published in New York in 1860.

Again, the "broad stand" is taken against the germ theory, of which the premises are wrong and the teachings of medical science are erroneous *ab initio*. As the cause of disease is the encumbrance of the system with effete, malassimilated foreign material, and personal susceptibility corresponds to the amount of the morbid matter within the organism, therefore disease itself is merely the process of the system to rid itself of these impurities, and it is in a last analysis a curative crisis.

The second book discusses the physiology and philosophy of fasting, the author inviting attention to the venerable dictum that men eat too much, choke and block the organic functions with food materials, and should relieve such conditions by fasting so that the system may have a chance to throw off impurities.

This gospel has been voiced by many. Burton writes: "Fasting is an all sufficient remedy of itself; for, as Jason Pratensis holds, the bodies of such persons that feed liberally, and live at ease, 'are full of bad spirits and devils, devilish thoughts; no better physic for such parties than to fast.' Hildesheim to this of hunger, adds, 'often baths, much exercise and sweat,' but hunger and fasting he prescribes before the rest. . . . As 'hunger,' saith Ambrose, 'is a friend of virginity, so is it an enemy to lasciviousness, but fulness overthrows chastity, and fostereth all manner of provocations.'" (*Anatomy of Melancholy*, pt. iii, sec. 2, mem. 5, subs. 1.)

The practical application of fasting is shown in a chapter on cases cured by this method, which has the same scientific value as an account of cures at Lourdes or of treatment by Christian Science. The author herein submits a new cause of paralysis: "It is the pressure over the nerves of unduly retained effete material." The theory that the sole function of food is the replacement of tissue, that it supplies no heat and no energy whatever, and that energy flows into the organism in some mysterious way from some external though unknown source is scarcely worth discussion in these columns. We are told that "sleep is that physiological condition of the organism in which the nervous system of the individual (in precisely the same manner as the electric storage battery) is being recharged from without, by the external, all pervading cosmic energy." Those who are not adepts on cosmic energy are incompetent to discuss this theory.

Anæmia is a curing process, we learn, because it is caused by overfeeding. Cancer is due to "an overplus of malassimilated material within the system," and should be cured by fasting in the initial stages. An unwonted conservatism is manifested in the statement that "overeating may be and probably is one of the chief causes of insanity to-day," though this mental attitude changes in his deduction from Kræpelin's histories that it was obvious that the forced feeding was the chief cause of the condition.

The author is in error in assuming that fasting does not appear absurd as a cure for all bodily complaints, even though he concedes that it may have its limitations, as in mental diseases or mechanical obstruction or interference. He begs the question in the statement that in deaths from starvation it is not the fasting but the mental condition that

etc.—that kills the individual. Throughout organic life privation of nutriment will cause death, and those pathologists who work in large cities are familiar with deaths due to starvation. Not only should the histories of famine epidemics indicate the influence of fasting in the causation of disease, but the employment of such a method would in many instances result in an exhaustion associated with toxæmia or acidosis that will terminate fatally.

*Studies in Laboratory Work.* By C. W. DANIELS, M. B., Camb., M. R. C. S. Eng., Director of the London School of Tropical Medicine, etc., and A. T. STANTON, M. D. Tor., M. R. C. S. Eng., D. T. M. and H. Camb., Demonstrator, London School of Tropical Medicine. Second Edition. Thoroughly Revised, with Many New and Additional Illustrations. Philadelphia: P. Blakiston's Son & Co., 1907. Pp. 491.

The first edition of Daniels's laboratory studies in tropical medicine is well known to all students of that branch as a good working guide for use in the field. Since the publication of the first edition, in 1903, the advances made in tropical medicine have been so marked that a new edition is most opportune. The activity in the line of tropical medicine, however, continues, and there are some things in the present edition that must be changed in the next. This statement applies more particularly to zoological nomenclature and the relation between the insect transmitters of protozoon parasites and the parasites which they harbor.

The new edition contains admirable analytical tables for the determination of mosquitoes, ticks, biting flies, tsetse flies, lice, and fleas. The analytical tables for the trematodes, cestodes, and nematodes are about the same as those in the first edition of the book.

The discussion of statistics has been given a special chapter, in which there is a consideration of the value of evidence of the existence of certain diseases when obtained from sources other than personal observation, the spleen test, the endemic index, the preparation of charts, etc. Dr. H. B. G. Newham contributes a section on water analysis.

We think that possibly it would have been better for the practitioner in the field had the authors tabulated the methods of using the different staining processes, giving a time limit for each step of the procedure. It has been our experience that directions for using stains and for employing chemical tests have to be very explicit if those using them for the first time are to get good results.

It appears to us that there are too many typographical errors for the second edition of a work of this kind.

The colored plates are the same as those in the first edition, but the figures in the text are more numerous and are very clear.

*Traité clinique des maladies de l'estomac.* Par le Dr. LUCIEN PRON (d'Alger). Paris: Jules Roussel, 1908.

After a surfeit of treatises on the stomach in which an exaggerated prominence is given to the chemical examination of the gastric secretions, it is a relief to turn to this excellent work, written more from the clinical standpoint—not, however, that the more modern methods of diagnosis have been neglected by Dr. Pron. They are given in sufficient detail, but are properly subordinated to careful study of the symptomatology and the older methods of

accurate bedside observation. These are now often somewhat neglected for the more fashionable laboratory methods, but are, we believe, of greater value to most practising physicians than the difficult quantitative analyses which occupy so much space in many recent books. Only a competent chemist is capable of making such analyses, and there is a good deal of cant and pretense in much of the assumed familiarity with them. As might be expected from a French author, the sections on diet are especially good, and contain many useful hints and practical suggestions as to the selection and cooking of food for dyspeptics. The American victim of cold storage processes and the queer commercial products which come out of cans and boxes will read with poignant interest these gastronomic chapters which emanate from a land where the intelligent preparation of real food is an art understood and practised in the humblest homes. Methods of treatment are considered with unusual fulness, there is a scholarly article on the relation of the stomach to other organs, and the book as a whole gives the impression of a large personal experience supplemented by diligent study of all the important special literature. If a minor criticism is permissible where there is so much to be commended, it may be said that the author's elaborate classification of functional disorders of the stomach appears to be somewhat strained and artificial.

*Die Funktionen der Nervencentra.* Von Prof. Dr. W. v. BECHTEREW, o. Akademiker, Direktor, der psychiatrischen und Nervenkrankheiten der medizinischen Akademie, Präsident des psychoneurologischen Institutes in St. Petersburg. Deutsche Ausgabe, in Verbindung mit dem Verfasser redigiert durch Dr. RICHARD WEINBERG, Professor der Anatomie in St. Petersburg. Erstes Heft: Einleitung, Untersuchungsmethoden, Rückenmark und verlängertes Mark. Mit 96 Abbildungen im Text. Jena: Gustav Fischer, 1908. Pp. 691.

This first volume of the German edition of Bechterew's general treatise on the functions of the nervous system is one of more than usual interest in the vast horde of recent works on the nervous system and its functions. It deals with the methods of investigation of the nervous system and the physiology of the spinal cord and medulla oblongata. It is almost a commonplace to state that activity in the investigation of the nervous system has never been more pronounced than during the last fifteen years. The newer methods of microscopical anatomy have given a definiteness and precision to physiological study that had before been lacking, and the almost impenetrable maze of anatomical structure, thanks to the researches of Weigert, Golgi, von Lenhossek, Cajal, Nissl, and Bielschowsky, has been boldly entered, and the results have been dealt with by such eminent physiologists as Sherrington, Ferrier, Munes, Goetz, Flechsig, and Luciani. It is with these correlations that this work deals.

We cannot enter into a detailed analysis of the work. It is too monumental. We can only point out its practical character, although deprecating its excessive verbosity. In no other work of a similar kind have there been brought together so many of the facts concerning the nervous functions. Thus, as an instance, the author, in treating of the tendon reflexes, departs from the usual line of a general description of what constitutes a reflex with a brief

schematic picture of the reflex arc, in that he discusses the actual nerve paths traveled in each reflex. The entire muscular and sensory physiology is handled in the same detailed and thorough manner.

This work is destined to be one of great importance in the history of our knowledge of the nervous system. It does not purport to be a work of original research, but it is a valuable compilation, admirably conceived and well executed.

*Syphilis.* A Treatise for Practitioners. By EDWARD L. KEYES, Jr., A. B., M. D., Ph. D., Clinical Professor of Genitourinary Surgery, New York Polyclinic Medical School and Hospital, etc. With Sixty-nine Illustrations in the Text and Nine Plates, Seven of which are Colored. New York and London: D. Appleton & Co., 1908. Pp. xxix-577.

The elder Keyes, who contributes a "foreword" to this volume, has long been known for the admirable clearness of his writings, and the son is not in the least his inferior in trenchant diction. The style, indeed, is one of the great charms of the book. The book is interesting throughout; perhaps of particular interest to most readers will turn out to be the section on *tabes dorsalis* and paresis. "Seeing these diseases from a syphilitic point of view," says the author, very frankly, "I naturally encounter only those of manifest syphilitic origin, and, accordingly, must side with those who believe *tabes* to be almost always syphilitic in origin, paresis frequently so." Further along he says: "Juvenile paresis and *tabes* are exclusively syphilitic." He adds: "Most authorities agree that syphilis is not the adequate cause of either malady. 'Syphilis and civilization,' says Krafft-Ebing. And this is the accepted doctrine." Evidently the author does not subscribe to the daring dictum that all *tabes* is syphilis, and our own belief is that he is right in declining to do so.

The initial chapter, *Syphilis in Relation to Public Health*, is impressive and strengthens one's hope that such agencies as the Society of Sanitary and Moral Prophylaxis may in a few years accomplish something substantial in the way of curbing the inroads of prostitution, whether professed or clandestine, on the physical and moral health of the community. Running all through the book, indeed, there is a wholesome undertone which will achieve much more in that direction than police raids or lofty legislation.

The book is very handsome in appearance, though the text is marred by an extreme of the "bobtailed" spelling, which, we presume, is the work of the publishers, not of the authors. We heartily commend Dr. Keyes's treatise.

*An Introduction to Vegetable Physiology.* By J. REYNOLDS GREEN, Sc. D., F. L. S., F. R. S., Fellow of Downing College, Cambridge, Late Professor of Botany to the Pharmaceutical Society of Great Britain, etc. Second Edition. Philadelphia: P. Blakiston's Son & Co., 1907. Pp. xx-459.

As the study of human physiology and pathology advances it becomes more and more evident that the fundamental processes are extremely simple and arrive at the complexity seen in human life only by countless series of generations of growth in structural complexity. It seems only yesterday that the animal physiologist became vitally interested in the problems of physical chemistry, of electrical dissociation in cells, of the intricate nature of cellular fer-

mentation, and of related subjects, all of which involve the most elementary forces of organic and inorganic life.

There has been a tendency to exaggerate the differences that exist in plant and animal life, which the author of this work wishes to show are unessential. There is a fundamental unity of all living substance. Protoplasm, in short, is the same material, whether we call it animal or vegetable. Its conditions of life and its immediate necessities must be practically the same, whatever its degree of differentiation in either direction. Differences of behavior and of structure are to be traced to differences of environment and habit of life more than to those of constitution.

It is not only by reason of these essential similarities that the study of plant physiology should constitute an essential feature in the curriculum of a modern medical school, and a work on plant physiology, one to be read by medical practitioners, but by virtue of the further significant fact that in plants, for the most part, the fundamental physiological processes, because of the simplicity of structure, may be the more readily comprehended and subjected to experimentation.

A good short handbook on plant physiology has not been attainable; those of Pfeffer, Sach, Jost, and Vines are too extensive, and MacDougall's is too elementary. This work of Professor Green's, whose work on fermentation is so well known to physiologists the world over, is admirably adapted to the purposes, and deserves a wide circle of readers.

*Atlas of Typical Operations in Surgery.* By Dr. PH. BOCKENHEIMER and Dr. FRITZ FROHSE. Sixty Illustrations from Water Colors by FRANZ FROHSE (Artist), Berlin. Adapted English Version by J. HOWELL EVANS, M. A., M. B., M. Ch., Oxon., F. R. C. S., England, Demonstrator of Operative Surgery at St. George's Hospital, London, etc. New York: Rebmam Company; London: Rebmam Limited. Quarto, pp. 252.

These superb plates depict high tracheotomy (three plates), hemicraniotomy (two plates), Bassini's operation for the radical cure of inguinal hernia (five plates), ligation of the lingual artery, von Bergmann's method of excision of the tongue (five plates), gastrostomy (two plates), excision of the larynx (five plates), resection of a rib, cellulitis of the hand (its relations), excision of the kidney (two plates), an operation for femoral hernia (two plates), removal of the vermiform appendix, transpleural laparotomy, urethrotomy and prostatectomy (three plates), cellulitis of the neck (its relations), suprapubic cystostomy, laminectomy (two plates), colostomy, enterostomy, anterior gastroenterostomy (three plates), resection of intestine (two plates), pericardiectomy, posterior gastroenterostomy, lateral intestinal anastomosis, excision of the rectum (two plates), operations on the biliary passages (three plates), thyroidectomy (two plates), cesophagotomy, removal of the breast, and operations on the trigeminal nerve and the Gasserian ganglion. In addition to the plates, there are numerous woodcuts of the various instruments and appliances that have been found useful in the operations. The explanatory text, though condensed, is clear and precise. The book is handsomely and substantially bound, and the typography is of the best. It seems to us that no progressive surgeon would be willing to be without it.

*Les Homosexuels de Berlin.* Par le Dr. MAGNUS HIRSCHFELD. Paris: Jules Roussel, 1908. Pp. 103.

This short contribution to the literature of sexual anomalies deals largely with the recent cause célèbre of Berlin, and in tone is a general defense of many practices allowed in ancient times, but more or less frowned upon in polite society, at least as regards avowed attitude.

*Practical Anæsthetics.* By H. EDMUND G. BOYLE, M. R. C. S., L. R. C. P., Assistant Anæsthetist to St. Bartholomew's Hospital, etc. London: Henry Frowde (Oxford University Press) and Hodder & Stoughton, 1907. Pp. viii-178.

We have here another of the series of excellent Oxford medical publications, several of which have already been reviewed in these columns. In this issue the entire subject of general anæsthesia is treated in a thoroughly practical manner, detailed instructions as to the best modern methods of administering nitrous oxide, ether, chloroform, and ethyl chloride, with the different anæsthetic mixtures, their indications as to preference and dangers, being fully described. Their author makes a point that ether is to be preferred in *inducing*, chloroform in *maintaining* anæsthesia. For prolonged surgical anæsthesia the best method in general is the sequence of nitrous oxide, ether, and chloroform. All directions are clearly given, and the book should be of special interest to the surgical hospital interne, who is too often lamentably deficient in his knowledge of the correct use of anæsthetics. The value of the text is enhanced by a number of very good illustrations.

*Nervous and Mental Diseases.* For Students and Practitioners. By CHARLES S. POTTS, M. D., Professor of Neurology in the Medico-Chirurgical College of Philadelphia, etc. Second Edition, Revised and Enlarged. Illustrated with 133 Engravings and Nine Plates. Philadelphia and New York: Lea & Febiger, 1908. Pp. vi-570.

The second edition of this manual makes its appearance in a greatly enlarged and amended form. To it has been added a chapter on mental diseases which has been entirely rewritten, and about fifty pages are devoted to mental troubles. In general the teachings in the first portion of the book on nervous diseases are in accord with those usually held by neurologists the world over, and, presented as they are in a very sketchy manner, they are particularly useful to beginners in this field of medicine. It is because of this didactic mode of presentation that the book has found considerable favor and will continue to be of service.

At the same time we think that the author could have improved his work considerably if a number of his statements had been made less didactic and more inclusive of the general biological point of view. It is impossible to analyze at this time the various features discussed and to point out some of the slight mistakes that have been made; but in general the latter have been few.

So far as the chapter on mental diseases is concerned, we feel that the author's point of view is strangely at variance with modern teachings. To Dr. Potts, insanity is *one* disease which shows itself under various phases. This is a distinct reversion to the idea almost, we might say, of Hippocratic days, and tends to perpetuate the confusion that already exists, not only in the mind of the layman, but in that of the physician, especially if he has had any

experience in mental disorders. To say that mental disorders are not diseases, but symptom groups alone, means very little, for, after all, diseases are nothing but symptom groups. Specific modes of reaction on the part of functional disturbances are just as truly diseases, if the proper concept of what constitutes a disease is borne in mind. Because our methods of analysis are as yet comparatively crude in the field of mental derangement is certainly no justification for relapsing into the *laissez faire* attitude adopted by the author in the second part of this otherwise very excellent manual. To maintain, for instance, that hysteria is a definite disease, whereas general paresis is only a symptom group, is ridiculous. All in all, however, the manual will be a very useful one for those for whom it is devised.

#### BOOKS, PAMPHLETS, ETC., RECEIVED

**Heredity.** By J. Arthur Thomson, M. A., Regius Professor of Natural History in the University of Aberdeen, Author of *The Study of Animal Life*, etc. With 49 Illustrations. New York: G. P. Putnam's Sons; London: John Murray, 1908. Pp. xvi-605.

**Nursing the Insane.** By Clara Barrus, M. D., Woman Assistant Physician to the Middletown State Homeopathic Hospital, Middletown, N. Y. New York: The Macmillan Company, 1908. Pp. x-409.

**Immune Sera. A Concise Exposition of our Present Knowledge Concerning the Constitution and Mode of Action of Antitoxines, Agglutinins, Hæmolytins, Bacteriolysins, Precipitins, Cytotoxines, and Oponins.** By Dr. Charles Frederick Bolduan, Bacteriologist, Research Laboratory, Department of Health of the City of New York. Second Edition, Rewritten. First Thousand. New York: John Wiley & Sons; London: Chapman & Hall, Limited, 1907. Pp. viii-154. (Price, \$1.50.)

**Typhoid Fever. Its Causation, Transmission, and Prevention.** By George C. Whipple, Consulting Engineer, with an Introductory Essay by William T. Sedgwick, Professor of Biology, Massachusetts Institute of Technology. First Edition. First Thousand. New York: John Wiley & Sons; London: Chapman & Hall, Limited, 1908. Pp. xii-407. (Price, \$3.)

**Diseases of the Nose, Throat, and Ear. Medical and Surgical.** By William Lincoln Ballenger, M. D., Professor of Otology, Rhinology, and Laryngology, College of Physicians and Surgeons, Department of Medicine, University of Illinois, etc. Illustrated with 471 Engravings and 16 Plates. Philadelphia: Lea & Febiger, 1908. Pp. viii-17 to 905.

#### Miscellany.

**An Appeal to the Medical Profession.**—The Legislature has passed a bill, Senate Bill No. 1033, creating a profession of optometrists, and it is up to the Governor to sign or not to sign as the merits of the case appeal to him.

It creates a board of examiners of "five persons who shall possess sufficient knowledge of theoretical and practical optics to practice optometry, and who shall have been residents of the State actually engaged in the practice of optometry for at least five years."

It provides that any person who has been engaged in the practice of optometry for two years next prior to the passage of the act may receive a license without examination, upon recommendation of the board of examiners.

This bill is an invasion of the sphere of medicine in one of its most important branches, and confers

privileges on certain people which, in accordance with the wording of the act, they are utterly incompetent to exercise.

The bill grants to opticians the right to adjust lenses to people's eyes in need thereof, and denies them the right to use drugs.

Without the use of drugs, in certain cases, even the most competent physicians cannot properly adjust lenses to the eyes, especially in children, and great harm can be produced by attempting such practice without using drugs.

The knowledge of optics alone, however extensive, does not render a person competent to do the work this bill would give opticians the right to do. To examine the eyes and adjust lenses one should have a knowledge of anatomy and physiology at least, but this bill provides only for a knowledge of optics. The many diseased conditions which may influence the eyes, and vision, are not considered at all. The ability to make a diagnosis is necessary to enable one to discriminate between visual defects due to diseases and those due solely to optical errors, both of which often exist at the same time, and this ability requires more than a knowledge of optics.

The passage of this act denotes gross and inexcusable ignorance on the part of members of the legislature, or an utter disregard of the welfare of the community.

It is a most vicious type of special legislation in that it permits an examining board of five members to discriminate between opticians who apply for certificates of exemption. The recommendation of this board is necessary before these certificates can be granted, and this board can limit its recommendations to a chosen few.

If the physicians of this State will go on record with the Governor, opposing this bill, it will never become a law. Will you write at once, urging the Governor to withhold his approval?

Very truly yours,

FRANK VAN FLEET, M. D.,

Chairman Committee on Legislation,  
Medical Society of the County of New York.

WALTER E. LAMBERT, M. D.,

Member Committee on Legislation,  
Medical Society of the State of New York.

**Resolution Adopted on the Death of Sister Louis Gonzaga.**—The medical board of St. Vincent's Hospital adopted, at a recent meeting, the following resolution:

After many fruitful years of continuous, abundant, and merciful labor in the cause of the poor and the suffering of the city, Sister Louis Gonzaga has passed along from an honored post of earthly duty to one of exalted station of reward in the world above.

Those who, heretofore, have been cheered by her gracious presence and genial smile, ever an earnest of beneficent desire and of a pure and humble spirit, will miss her benign presence and bountiful benevolence more and more as time endures. Sister Gonzaga's devotion to duty was not limited by measure nor modified by method; it was free and boundless. Her activities were tireless, and the products of her efforts were worthy of the emulation of those hav-

WOOD, C. E., Assistant Surgeon. Relieved from duty at Stapleton, N. Y., and directed to proceed to Chicago, Ill., reporting to the medical officer in command for duty and assignment to quarters.

#### Board Convened.

A board of medical officers was convened to meet at Seattle, Wash., April 24, 1908, for the purpose of making physical examination of an alien immigrant. Detail for the board: Passed Assistant Surgeon M. W. Glover, chairman; Assistant Surgeon C. W. Chapin; Acting Assistant Surgeon F. R. Underwood, recorder.

#### Army Intelligence:

*Official list of changes in the stations and duties of officers serving in the medical department of the United States Army for the week ending April 25, 1908:*

BANTA, W. P., First Lieutenant and Assistant Surgeon. Granted leave of absence for four months.  
CARTER, E. C., Major and Surgeon. Granted leave of absence for three months, to take effect about June 1st.  
CRAIG, C. F., First Lieutenant and Assistant Surgeon. Granted leave of absence for two months, to take effect about July 1st.  
DAVIS, W. R., Captain and Assistant Surgeon. Granted leave of absence for fifteen days.  
FISCHER, H. C., Major and Surgeon. Relieved from duty at Fort Logan, Col.; ordered to Washington, D. C., for instructions; thence to Fort Slocum, N. Y., to familiarize himself with certain methods pertaining to the examination of recruits; and thence to Columbus Barracks, Ohio, for duty.  
GOSMAN, G. H. R., Captain and Assistant Surgeon. Relieved from duty at Columbus Barracks, Ohio, and ordered to Fort Morgan, Ala., for duty.  
LEWALD, LEON L., Captain and Assistant Surgeon. Relieved from duty at Fort Slocum, N. Y., and ordered to Columbus Barracks, Ohio, for duty.  
POWELL, J. L., Lieutenant Colonel and Deputy Surgeon General. Granted an extension of eight days to leave of absence.  
RAYMOND, H. I., Major and Surgeon. Relieved from duty at Columbus Barracks, Ohio, and ordered to Fort Sam Houston, Tex., for duty.  
RAYMOND, T. U., Major and Surgeon. Granted leave of absence for one month; order for Fort Sam Houston, Tex., amended; will proceed to Fort Logan, Col., for duty.  
ROCKHILL, E. P., Captain and Assistant Surgeon. Relieved from observation and treatment at the General Hospital, Fort Bayard, N. M., and from further duty in the Philippines Division, and ordered to duty at that hospital.  
VOSE, W. E., Captain and Assistant Surgeon. Relieved from duty at Columbus Barracks, Ohio, and ordered to Fort Slocum, N. Y., for duty.  
WILLIAMS, A. W., Captain and Assistant Surgeon. Granted leave of absence for two months; at the expiration, ordered to proceed to Fort H. G. Wright, N. Y., for duty.

#### Navy Intelligence:

*Official list of changes in the medical corps of the United States Navy for the week ending May 2, 1908:*

BACON, S., Assistant Surgeon. Appointed assistant surgeon from April 11, 1908.  
BAKER, M. D., Pharmacist. Ordered to duty at the Naval Medical School Hospital, Washington, D. C.  
BIELLO, A., Appointed an assistant surgeon from April 11, 1908.  
COOK, F. C., Surgeon. Detached from the Naval Academy and ordered to the North Carolina when commissioned.  
HOUGH, F. P. W., Assistant Surgeon. Appointed an assistant surgeon from April 11, 1908.  
PLUMMER, R. W., Surgeon. Commissioned a surgeon from February 23, 1908.  
RHODES, G. C., Assistant Surgeon. Appointed an assistant surgeon from April 11, 1908.  
ROTHGANGER, G., Surgeon. Granted sick leave for three months when discharged from treatment at the Naval Hospital, New York.  
SPEAR, D. A., Assistant Surgeon. Ordered to duty at the Naval Hospital, Washington, D. C.

## Births, Marriages, and Deaths.

#### Married.

COOK—HARE.—In Philadelphia, on Tuesday, April 28th, Mr. Arthur B. Cook, United States Navy, and Miss Marie Amory Hare, daughter of Dr. Hobart Amory Hare.  
EGAN—GENSLER.—In Chicago, on Monday, April 20th, Dr. J. J. Egan and Miss Thekla Gensler.  
GREENLEAF—MCLELLAN.—In Washington, D. C., on Thursday, April 30th, Dr. Henry S. Greenleaf, Medical Department of the United States Army, and Miss Carrie McClellan.  
HIGGINBOTHAM—PHILLIPS.—In Boston, on Tuesday, April 21st, Dr. Fred A. Higginbotham, of Cambridge, and Miss Maud E. Phillips.  
JAMES—JONES.—In Utica, New York, on Wednesday, April 22d, Dr. F. W. James and Miss Lillian Mae Jones.  
LUNG—DE PEYSTER.—In New York, on Tuesday, April 28th, Dr. George A. Lung, United States Navy, and Miss Helen Van Cortlandt de Peyster.  
MARTER—WEST.—In Los Angeles, California, on Saturday, April 25th, Dr. Linnaeus Escher Marter and Miss Emma Brown West.  
O'CONNOR—DE WITT.—In Roxbury, Massachusetts, on Wednesday, April 22d, Dr. Victor F. O'Connor and Miss Lila M. De Witt.  
ZALESKY—DISMUKES.—In St. Augustine, Florida, on Monday, April 27th, Dr. William John Zalesky, United States Navy, and Miss Elizabeth Gibbs Dismukes.

#### Died.

ALDRICH.—In Cleveland, Ohio, on Wednesday, April 29th, Dr. Charles J. Aldrich, aged forty-six years.  
COCHRAN.—In Brooklyn, N. Y., on Wednesday, April 29th, Dr. Alexander Cochran, aged seventy-six years.  
CRAIG.—In Cincinnati, Ohio, on Thursday, April 23d, Dr. A. G. Craig, of Vevay, Indiana.  
DODD.—In North Babylon, Long Island, New York, on Tuesday, April 28th, Dr. E. Dodd, aged sixty-nine years.  
EARLES.—In Milwaukee, Wisconsin, on Tuesday, April 28th, Dr. William Henry Earles, aged fifty-five years.  
ENGLAND.—In Winnipeg, Canada, on Friday, April 24th, Dr. W. S. England, aged forty years.  
FARRINGTON.—In New York, on Monday, May 4th, Dr. Joseph Oakley Farrington, aged seventy-eight years.  
GASKILL.—In Bourbon, Indiana, on Tuesday, April 21st, Dr. I. C. Gaskill.  
HARRIS.—In Kansas City, Missouri, on Wednesday, April 22d, Dr. E. B. Harris, aged seventy years.  
HAY.—In Jamaica Plain, Massachusetts, on Sunday, April 26th, Dr. Gustavus Hay, aged seventy-eight years.  
HEIDEMANN.—In St. Louis, Missouri, on Saturday, April 25th, Dr. J. H. Heidemann, aged sixty-three years.  
HUTCHINSON.—In Wakefield, Massachusetts, on Tuesday, April 21st, Dr. Marcello Hutchinson, aged fifty-eight years.  
LORENZO.—In Monroe, Michigan, on Wednesday, April 22d, Dr. Godfrey Lorenzo, aged seventy-nine years.  
MILLER.—In Harrisburg, Pennsylvania, on Monday, April 27th, Dr. Jacob A. Miller, aged seventy-one years.  
MORTON.—In Baltimore, Maryland, on Monday, April 27th, Dr. J. Cook Morton, aged forty-four years.  
NICKLES.—In Cincinnati, Ohio, on Tuesday, April 21st, Dr. Samuel Nickles, aged seventy-three years.  
RALSTON.—In Pittsburgh, Pennsylvania, on Sunday, April 26th, Dr. Curtis Ralston, aged thirty-two years.  
ROBINSON.—In Monongahela, Pennsylvania, on Sunday, April 26th, Dr. F. C. Robinson, aged eighty-eight years.  
SCAMMELL.—In St. John, New Brunswick, Canada, on Saturday, April 25th, Dr. J. Harris Scammell.  
SHAW.—In Hoosick Falls, New York, on Thursday, April 30th, Dr. J. C. Shaw, aged sixty years.  
SMITH.—In Hornell, New York, on Sunday, April 26th, Dr. L. B. Smith, aged fifty-seven years.  
STIEMER.—In Hillsdale, Michigan, on Saturday, April 25th, Dr. Alexander Stierner.  
TERHUNE.—In Brooklyn, on Thursday, April 30th, Dr. James Jackson Terhune, aged sixty-four years.  
WATSON.—In Chicago, on Friday, April 24th, Dr. Harry Watson, aged twenty-five years.  
WILLOUGHBY.—In Colborne, Ontario, Canada, on Tuesday, April 28th, Hon. Dr. William Armson Willoughby, aged sixty-four years.

#### THE DIAGNOSTIC VALUE OF SYMPTOMS OF THE LARYNX, PHARYNX, AND NOSE, IN NERVOUS DISEASES.\*

BY THOMAS J. HARRIS, M. D.,  
New York.

No more interesting and timely subject could have been selected for consideration to-night than the diagnostic value in general medicine of symptoms referred to the upper air passages, especially the diseases specified in this symposium. At the same time the subject is so broad and far reaching that any presentation of it in the comprehensive way which is demanded will be prevented by the time at our disposal. Particularly true is this in the matter of nervous diseases. Certain phases of the subject have served to provoke unending discussion and debate in the early years of laryngology, and the literature thereon is well nigh inexhaustible.

Any attempt at entering at length upon a consideration of these is neither desirable nor possible. An intelligent appreciation, however, of the diagnostic value of such symptoms demands at least a cursory review of what has been agreed upon after all controversial questions are omitted. It may be said at the outset that affections of the nervous system present symptoms of value and importance from a diagnostic standpoint, in the throat and nose, whether they be true organic affections or only functional disorders such as the so called neuroses. Of the two, the organic affections are much more the important. They show themselves chiefly in the larynx and are in the form of either sensory or motor disturbances. As is well known, the nerve supply of the laryngeal muscles is derived from the vagus, the inferior or recurrent laryngeal nerve conveying motion to all except the cricothyroid, which is supplied by the superior laryngeal, which is also the nerve of sensation. The only dispute in this connection has been whether the spinal accessory shares in this function to a limited extent. It has now generally been agreed that this is not the case. It must further be remembered that these nerves are called upon to perform a double function, first to open the glottis during respiration, and second to bring the cords together for the purpose of phonation. The first is accomplished through the abductor muscles, the two cricoarytenoid (posterior); the second function, through the adductors,

including the cricoarytenoid laterales, the transversus and the thyreoarytenoidii interni.

There can be little question that the centre for respiration is in the medulla, in all probability on the floor of the fourth ventricle, and is not under the control of the will. That there is a second centre for phonation in the cerebrum is also now generally admitted. Indeed in 1884 Krause demonstrated such a centre in the anterior lower extremity of the anterior central convolution of each hemisphere, irritation of which on either side produces bilateral adduction. This observation has subsequently been confirmed by various investigators. The important corollary is, however, to be noted that a lesion involving one centre alone is not sufficient to suspend movement in the larynx, though this occurs when both centres are involved. And in spite of the persistent and ardent attempts made to prove such a direct relation between the cortex and larynx, the summing up of Wright made ten years ago<sup>1</sup> represents the views of most scholars to-day, viz., "there has been no case reported in man of a cortical lesion accompanied by laryngeal paralysis in which the possibility, and few in which the probability, of involvement of the nervous tract below could be excluded. We must, therefore, in view of the positive evidence in animals and the negative evidence in man, admit that Semon's declaration of the nonoccurrence of cortical laryngeal paralysis in man is probably correct." We are accordingly forced to limit the scope of such laryngeal symptoms, from a diagnostic standpoint, to lesions of the medulla or below. When such symptoms are considered we at once find that the motor manifestations are by far the most striking. These may represent either excess or diminution of action. Excess of action is seen in spasms which may be tonic or clonic. Tonic spasms may take the form of a, spasms of the larynx; b, laryngeal crises; c, ictus laryngis. Clonic spasms as a, rhythmic twitchings; and b, tremors. Where an organic nerve lesion is present, it is most frequently one of diminished action or paralysis. These paralyses may involve the superior or the inferior laryngeal nerve. A paralysis of the former alone, causing a failure to respond on the part of the cricothyroid, is exceedingly rare. Mygind has collected reports of thirteen cases, four of his own. Three of these latter showed bulbar symptoms, and in one a degeneration of both superior laryngeal muscles was found on autopsy. A study of paralyses of the inferior laryngeal will reveal that they almost without ex-

\*Read before the New York Academy of Medicine, April 15, 1908.

ception involve the cricoarytenoideus posticus at the onset and only at a late stage of the disease, if ever, attack the adductors. This striking fact was first set forth by Sir Felix Semon in an elaborate paper on the subject, and has since been known as Semon's law. Its clinical significance is at once apparent. A posticus paralysis, which, with the cords immobile in the median line and their free borders taut, would mean, in all probability, a central nerve lesion. If now the picture should in time change to one showing the cords in the so called cadaver position, that is, midway between inspiration and expiration with concave borders, we would know that the entire recurrent nerve has been involved, pointing to the progressive character of the lesion in the bulb. This dictum of Semon has been productive of much independent research which has, on the whole, served to establish its correctness. Onodi has shown the presence of separate fibres in the nerve. Fränkel has demonstrated that when the nerve is frozen, the adductors fibres first succumb. Hooper has found a similar condition when ether was used, and Massini, when he employed chronic acid. Krause endeavored to experiment on animals to show that this apparent paralysis may, under certain conditions, be due to a reflex contraction of the laryngeal muscles. This theory has, however, been abundantly disproved by the fact, among others, that at least one case of posticus paralysis has shown at the necropsy a true atrophy of the cricoarytenoideus posticus. Finally, Grabower has discovered that the nerve endings in the adductors differ morphologically from those in the adductors, pointing to a difference in their function, the one being concerned with phonation, while the others has to do with respiration. Indeed, Semon believes in a "reflex tonic spasm in the posticus muscle constantly present under the influence of the respiratory centre, which serves to keep the glottis always open." The existence of such a reflex would serve, in his opinion, to explain the failure, first, of the adductor fibres in a central lesion in conformity with the "physiological law that irritability of afferent nerves is exhibited earlier than of efferent nerves." Much remains, however, to be done to reconcile seeming discrepancies, as is evidenced by the fact that cases of posticus paralysis have been observed for years where no change in the position of the cords took place.

With this hasty summary of the present day views on the innervation of the larynx, for which we are largely indebted to Curtis's translation of Fredrich's admirable work on *Rhinology, Laryngology, and Otology, and Their Significance in General Medicine*, we shall proceed to consider briefly how we may make use of them in a practical manner in diagnosis. As has been previously stated, this applies chiefly to affections of the medulla and below, although it is true that cerebral hæmorrhage, tumors, abscess, gummata, and pseudobulbar palsy may produce motor changes in the larynx when extensive enough or properly situated.

*Tabes Dorsalis.*—Of the affections, situated in the cord, locomotor ataxia probably presents symptoms more often than any other. These may at times show themselves in the nose by disturbances of the olfactory nerve, such as anosmia or parosmia, but

usually they are limited to the larynx. Of these, some form of paralysis is comparatively common. Gerhardt found seventeen cases in 122 tabetics. Of these, eleven patients showed a posticus involvement, five bilateral, while three had paralysis of the entire recurrent. Semon's statistics are similar, fourteen cases in 100, eleven of which involved the postici, showing an overwhelming preponderance of adductor palsies. In a word, unilateral or bilateral posticus paralysis may be regarded as characteristic of tabes, and from the table of Berger of seventy-one cases of laryngeal palsies found in tabes, the bilateral form is nearly as common as the unilateral. The voice in the latter variety may not show any change, and accordingly such a condition is undoubtedly overlooked unless a systematic examination is made. Indeed, even in the bilateral form, the one symptom is gradually increasing inspiratory dyspnoea, with expiration unaffected. As is well known, this may lead to pronounced asphyxia, in time demanding tracheotomy.

Even more interesting are the various forms of laryngeal motor irritations in tabes. These include (a) ataxia of the cords, a name applied to a condition in which the cords execute irregular movements during phonation and deep respiration, giving rise to the characteristic scanning speech; and (b) laryngeal crises. These, like the palsies, may occur very early in the disease, preceding even the ocular manifestations. The laryngeal crisis is characterized by the simultaneous involvement of all the respiratory muscles, and so differs from an ordinary spasm of the larynx, where only the laryngeal muscles that suffer. It may arise without cause or as a result of a slight local stimulation, such as swallowing or touching the throat. It begins with a tickling or burning in the pharynx, followed by a choking sensation. A loud strident inspiration is heard, followed by a short puffing expiration. The patient gives rise to a cough, which is said to resemble that of whooping cough. While attacks are not usually regarded as dangerous, five fatal cases have been reported. Sensory disturbances in connection with tabes are rare.

*Multiple Sclerosis.*—Multiple sclerosis of the brain and spinal cord will produce symptoms in the larynx almost, if not quite, as frequently as tabes. These have been exhaustively studied by Löri, who followed several cases clinically for years. The common symptom present was a delay in the muscular action. This may take the form of a tremor in phonation. With this goes an abnormal tendency to voice fatigue. After a short use, the voice entirely fails. There will be noted also a scanning speech with frequent interruptions by high pitched explosive sounds. Because, too, the adduction is not complete, the voice is often raspy or hoarse. Finally, we occasionally meet with true paralyses, usually of the adductors. We have recently seen a woman of seventy years, where a diagnosis of laryngeal paralysis had been made because of the weakness of the voice. There were here the symptoms just mentioned, of scanning speech, voice fatigue, and hoarseness, all indicative of a disseminated sclerosis.

*Spasmodic.* Laryngeal symptoms, also motor in nature, and reduced reflex irritability of the

posterior pharynx wall are not uncommon in syringomyelia. Forty cases of paralysis have been collected by Iwanow up to 1907, usually involving the posticus on one or both sides, and occasionally the internus muscle as well. It was on account of the associated paralysis of the trapezius muscle in some of these cases that it was thought at one time that the spinal accessory sent fibres to the larynx.

*Progressive Bulbar Paralysis.*—Progressive bulbar paralysis, often known as glossolabiolaryngeal paralysis, is especially characterized, as the latter name implies, by symptoms referable to the tongue, lips, and larynx. While those of the tongue are wont to be very constant and usually appear early, producing difficulty in speech, increased later by an associated atrophy of the lip muscles, laryngeal paralyses, though important when present, do not occur with any such constancy. They may be the result of paralysis, either of the postici or of the entire recurrent, and may be unilateral or bilateral. Any serious involvement of the muscles here taken, especially in connection with abolishing of the pharyngeal reflexes, may permit the entering of food into the bronchi and so give rise to an inspiratory pneumonia.

*Progressive Muscular Atrophy.*—Progressive muscular atrophy will very commonly show some symptoms in the pharynx or larynx. These are usually of the nature of a paralysis, either of the entire throat and larynx or more often of the larynx. Here a unilateral posticus paralysis is most frequently met with. Occasionally an anæsthesia of the pharynx is also present.

*Neuroses.*—The functional nervous affections which show themselves in the upper air passages are the various neuroses. Of these we shall briefly consider only the two most commonly met with, paralysis agitans and hysteria.

*Paralysis Agitans.*—Paralysis agitans, in a considerable number of cases (five out of twelve cases in one series examined), gives rise to symptoms in the larynx. These are wont to be motor in character. Twitching movements of the cords will be noticed in phonation, and also as a rule in respiration, thus being distinguished from the tremors of multiple sclerosis. The epiglottis may share in the involvement. The speech is also at times scanning, and there is wont to be a sudden change from the high to the low pitch.

*Hysteria.*—Hysteria, as is generally recognized, will give rise to symptoms of one kind or another in the nose and throat in not an inconsiderable number of cases. These may be either sensory or motor. Sensation is often affected. Anæsthesia of the mucous membrane of the nose and pharynx is frequent. It is usually not general, affecting only certain definite areas. The septum is wont to escape as well as the larynx. Hyperæsthesia and analgesia of the pharynx are even more frequent and take the form of a choking sensation, tickling, feeling of a foreign body, and the tumidular globus hysteriens. These often result from some slight trauma, and of themselves may cause by the coughing organic changes in the throat. Hysterical motor symptoms are wont to affect particularly the muscles of the larynx. The most important of these are—

of a preceding catarrhal condition. It may be the first and only sign of hysteria. The clinical picture resembles the spasm which follows occasionally applications to the larynx. There is a series of long drawn out inspiratory whistles, followed by a short, loud expiration, attended by more or less severe dyspnoea, and complicated at times by general convulsions. It differs from the spasm attending an organic lesion by not involving any of the respiratory muscles. The appearance of the cords in the mirror during the attack suggests a posticus paralysis, but when the attack is over they resume their normal position.

(b) *Nervous Laryngeal Cough.*—Nervous laryngeal cough, often referred to as chorea of the larynx, shows, as all the other laryngeal manifestations of hysteria, a lowered vitality, together with heightened nervous irritability. While more generally met with in women, it occasionally occurs in young boys, as we have seen at least twice. Gottstein distinguishes two forms, 1, periodic; 2, continuous, rhythmic. It may persist for hours, or even at times days and weeks, but usually ceases during sleep, eating, and drinking; and only rarely seems to affect the general health seriously. The sound of the cough is characteristically unmelodious, resembling a bark. The cords are seen in the laryngeal mirror to come together at the moment of cough, but different from the picture in the usual cough, they appear very lax. There is also wont to be more or less of a distinct vibration on expiration. The glottis is not entirely closed, as is shown by the absence of cyanosis. 3. Disturbances of coordination are especially interesting. These may affect either the function of 1, respiration or that of 2, phonation, very rarely, if ever, both. As in similar conditions depending on an organic lesion, they take the character of either over action—spasm—or under action—paresis. Cases where respiration is affected are very rare; Treupel has collected seven. The picture, as described by him, is one where the glottis opens on inspiration, succeeded by a pause when the cords are strongly adducted. There is then an expiratory opening of the glottis, complicated by an initial closing, then a pause when the cords resume their normal position. The symptoms of the attack vary in their severity. There is usually great inspiratory dyspnoea, often accompanied by cough; and the beginning is marked by a long drawn, audible sound of inspiratory spasm. The face shows anxiety and fear of suffocation. The attack ceases during sleep.

*Disturbances of Coordination During Phonation.*—These are more common. (a) *Dysphonia spastica* is a term employed to describe the spastic form here. As long as the patient makes no attempt to speak the larynx appears normal, but the moment he tries to make any sound the adductor muscles come spasmodically together and the clunk of the glottis is lost. The patient may be able to get out a few words or utterly fail to produce a sound. Much more frequently still we meet with the (b) parietic manifestations of incoordination in phonation, known as aphonia. This very common manifestation of hysteria is the result, as a usual thing, of a paresis of all the adductors and tensions of the larynx, occasionally of the transversus and rarely of the transversus and internus muscles. The picture

(a) *Laryngeal Spasm.*—This is often the result

is often a changing one. The cords may for a brief moment come together. The false cords meet entirely in many cases.

*To Conclude.*—While in this hurried presentation of the subject we do not pretend to have included all the various nervous affections showing themselves in the region under discussion, we feel that enough has been said to show two things: 1, That pharyngolaryngeal symptoms in nervous diseases are deserving of more attention on the part of the neurologist than they have received up to the present time. And 2, that no field offers greater opportunity to the laryngologist for original study and research than that which embraces the innervation of the larynx.

# HYSTERIA AND THE REEDUCATION METHOD OF DUBOIS.\*

BY SMITH ELY JELLIFFE, M. D., Ph. D.,  
New York,

Visiting Neurologist to the City Hospital; Clinical Professor of  
Psychiatry, Fordham University.

I have been asked to discuss the subject of the Dubois reeducation method in psychotherapy, as applied to the psychoneuroses, and I make this attempt fully cognizant of the necessary shortcomings that such a task will reveal. First, with reference to the time that such an exposé would require in order to do the subject justice, which is all too short, and secondly, recognizing my own deficiencies for such a task.

The gradual growth of the principle and application of psychotherapy is a fit subject for the essayist's art. The entire history of medicine is closely interwoven with the development of what is so often called the soul life and with its expressions in religion, and the insufficiencies of thought have been reflected in both. Superstition and faith are twins, brothers of the same family, and as Magnus has well said, both originate in a sense of the inadequacy of human science in the face of natural phenomena demanding an interpretation. The early human mind, all human mind, in the attempt to explain has created an ethical requirement reaching out beyond the comprehension of the individual to a firmer understanding which it has called faith.

Faith, in my opinion, is one of the corner stones of psychotherapy, and hence the method of my introduction: "A new faith, separated, however, from superstition, with which it has too often been associated, is in the simplest of terms the expression of what it is desired to impart by the reeducation method—a faith raised to the level of reason and of knowledge, so far as we may be able to see it, and so far as the intelligence of the patient may be able to grasp it, is the aim of the psychotherapist in using the reeducation method"—I speak at this time in symbols only.

In the earliest phases of the so called temple sleep, I take it we see one of the most primitive expressions of a medicotherapeutic application of the principles of psychotherapy. A careful reading of the ancient theologies no doubt reveals other procedures closely allied, but for our present

purposes, the psychical side of the therapeutics of the priests of the pre-Hippocratic era, in which simple, abiding, childlike, unreasoning faith was the master key, and which has persisted in smaller and smaller degree to our own times, suggests the open door to the present day developments of an old, old idea.

It would be impossible for me, in this short space of time, to trace the course of the leading strings down through the centuries, but I bring to your minds the fact that there have been such, since one of the fundamental features in the therapeutic art of the true mental scientist is the need for the recognition of primitive features in the mind stuff of his patients, who are in need of educating if a synthesis is to be brought about sufficient in degree to meet the demands of the situations in which they may be placed.

Just what classes are in need of psychotherapy in some of its forms, is not my province to discuss. The breadth of the foundation laid down by Dubois precludes even the mention of the different forms of disorder in which the mind disturbance is the primary or contributory factor.

Recognizing the danger that I may beat all about the bush and raise no game, I shall purposely limit my remarks to the consideration of one particular type of reaction which, although hampered by the misinterpretation of ancient and even our own times, must needs blindly grope about in its protean and bizarre aspects as hysteria.

I am led to develop some of my own notions concerning hysteria, because, although recognizing that I shall express them in the most general of terms, should such thought reflect a fairly accurate approximation of the situation, it may be at once appreciated why the psychotherapeutic principle of education is the one best adapted to give results which may be hopefully regarded as permanent.

At the outset I desire to state a position that does not regard hysteria as a disease, or a malady, due to a specific disease process. I regard it rather as a collection, in an adult individual, of primitive traits of psychological response to psychopsychical factors. From the ontogenetic aspect one might express it that hysterical individuals are grown up children; from the standpoint of phylogeny, they are educated, or better, instructed savages. According to the proportion of these childish, or atavistic traits, which may be present in an individual, we find the symptom picture of hysterical traits, of the hysterical temperament, of minor hysteria, or of major hysteria; not that major hysteria represents any greater proportion of these reactions than others, but their manifestation in the psychomotor zone makes them the more striking.

I feel that I am not alone in holding that all of the efforts thus far put forth to make all of the innumerable troubles qualified as hysteria to fit into one category as a morbid entity have been fruitless. Hysteria considered as an entity appears like a gigantic Proteus and escapes all definitions. Seeking to define hysteria by the description of all its manifestations, different authors have been led to include the entire symptomatology of nervous diseases in their definition.

Bernheim, Schwyder, Binswanger, Dubois, and

\* Contributions to the Dynamics of Psychotherapy, New York Neurological Society, February, 1928.

many others have protested against this nosological conception, and the former reserves for the crises alone the term hysterical, giving to all the other troubles considered as characteristic of hysteria (stigmata, sensory motor troubles, visceral, etc.) the value of those manifestations having the general character of the psychoneuroses.

We are at one with Bernheim when he says, "hysteria is not a morbid entity," but, in his opinion, the crises constitute the abnormal psychical process to which one cannot without inconvenience apply the denomination hysterical. They can appear episodically in certain individuals; they are often widely enough extended, and continuous enough to permit of our speaking of them as the hysterization of the mentality. All in all, hysteria is the psychopathic manifestation par excellence, the most primitive expression, the most common of the inherent weaknesses of the human personality.

Hysterical modifications appear in mentalities very different one from another. They may be present in the gay and careless infant, in the sensible and impressionable woman, in the anxious and morose man, modeling themselves exactly on the habitual temperament. These psychical characters may be summarized more or less didactically as follows: Instability is a primary hysterical trait. This instability is particularly prominent in the field of the emotions—emotional lability, Kräpelin calls it; depressive states alternate rapidly with periods of exaltation; at one moment the hysterical patient is irritable and over impressionable, the slightest cause giving rise to a flow of tears; again, they are cold, indifferent, and cruel. At one moment intriguing, putting everybody by the ears, accusing others, then again overcome with self reproaches for their own wickedness. In their activities the same variability is manifest. At one time they are filled with an almost pathological (manic) energy; again they show its antitype, an absolute inability to do anything.

A second trait is the marked influence of suggestion. Babinski believes that a marked pathological alteration of this one factor is enough in itself to explain all the phenomena of the hysterical reaction.

A third trait, negativism, flows as a corollary from the second. In the terms of Bleuler's interpretations of negativism it is a necessity consequent on pathological suggestibility.

The egocentric nature is a fourth feature. The attention is fixed almost pathologically on the ego, and the constant search for changes within the person's own body on which to hang complaints is pursued with a definite pleasure and refined meditation. The slightest sensation is caught hold of and magnified. The pains of others, however, are not felt at all, and jealousy and envy arise if other pains are considered of moment to the neglect of theirs. To be sick and the centre of the stage becomes a life work, and a theatrical apprenticeship, with masterly training under the suggestive tutelage of many physicians, usually gives a finished artist in the end.

This pathological egocentricity leads to a number of secondary attributes, all very primitive in their nature. The strutting war chief, proud of his feathers and paint, is showing in his way the self-assertive features that the hysterical patient shows in his at-

tempts to create a sensation. Her romantic accusations, sensational confabulations, self mutilations, and refined theatrical attempts at suicide, all have their real motive power in this desire to be the observed of all observers. Lies, disfigurements, slanderings, stealing, and other crimes are not too much to bring this about. Simulation, in all its various aspects, becomes a useful adjunct in this mechanism to make the limelight constantly play on the individual's acts.

Practically all physical signs result from the second factor of suggestibility, but the more complete analysis of these is apart from our subject. We are confining ourselves to the mental mechanism of these psychic children.

We should note the different characters offered by infantile, male, and female hysteria by the exaggeration of certain psychical mechanisms existing in a more or less marked degree in all individuals. The mental make up of a person may show modifications of a hysterical character which, though often transient and accidental, may sometimes be so pronounced as to constitute a distinct clinical form of a psychoneurosis.

Hysterical manifestations may moreover appear in connection with the more frank insanities (dementia præcox, manic depressive, various degenerative psychoses); they have even been noticed along with general paresis. They may also be found associated with other organic affections of the nervous system—cerebral hæmorrhages, tumors of the brain, tumors of the cord—they may make part of the clinical picture of certain intoxications (alcoholic, carbon dioxide, sulphonal, bromides, analgæsic aniline derivatives). Finally they impress upon certain purely neurosthenic conditions certain characteristics which justify the term *hysteroneurasthenia*.

It is not difficult to perceive why such hysterical manifestations should accompany physical disease; indeed it is in strict accord with our hypothesis that the superior individual is one who by intelligence and by training has developed past his hysterical infancy, or youth, but let intercurrent disease reduce his resistance, or sink the level of his nervous tension, as Janet would express it, and a partial reversion to primitive traits is to be expected. To be a hysterical old woman is another way of saying that an advancing arteriosclerosis has broken down the synthesis of strong manhood and left the disorderly uncontrolled connections of youth, or infancy.

In the normal mentality of a child, one may find the ground plan as it were of most hysterical manifestations, and to speak of a physiological infantile hysteria, while it does not explain, is yet tenable. Hysteria in an adult is closely allied to certain psychic conditions which represent, in fact, a mental retrogression toward the infantile type, of which the chief characteristic is the lack of logical judgment. The hysterical individual is led by the initial defect into a system of autosuggestions which may end up in a profound disturbance of his personality.

The importance of moral causes in the development of hysterical states cannot be overestimated. From this point of view we may consider hysteria as a series of abnormal reactions of the individual to the exigencies of life. These are small

of reaction are often the consequence of the fetters, or the obstacles which the moral and social order imposes upon the expression of the natural tendencies of man and show themselves the more strongly the closer the man approaches the child viewpoint.

In a general way, one may say then with Schnyder that the hysterical modifications of the mentality have as their starting point a defect of judgment, or lack of mental synthesis, which leads to an erroneous conception of real situations, and a consequent inability to adapt oneself to them. Hysteria is, in the first place, a disease of the evolution of the human mind. It represents a break in the development of the mentality. Therefore, hysteria in its pure form is a disease of youthful individuals, just as it is a disease of humanity in its infancy. One rarely meets it in the adult whose mentality has reached its full development. Its reappearance in the years of involution is self evident.

With Schnyder, I believe that one can show that from the phylogenetic point of view, hysteria may be the attribute of evolutionary phases of humanity; in history it appears to blossom each time that the aspirations of the human mind have been held back and repressed by the laws of the established order of the age. Namely, in those periods which have preceded the great moral, social, and political revolutions. Schnyder asserts that the best example of this is seen in the Middle Ages, which was the classical period of "hysteria of the masses," or, as Hellpach has expressed it, "the period of the infancy of individualism," where all the forces of conservatism, with the Church at their head, were struggling in vain to withstand the inroads of newer and better adapted, moral standards of individualism.

I do not feel at one entirely with Hellpach's statement concerning the attitude of clericalism toward the whole movement. What he says is only a half truth, too biased and perhaps prejudiced by the literature of anticlericalism. I prefer to see it in the light of the upward impetuous striving of human effort and culture apart from any preconceived notions we might have regarding efforts at repression, as coming from one side alone. The driving, forward element was just as evident in ecclesiastical as in nonecclesiastical circles, and the bonds of conservatism were not all of religious forging.

With Schnyder and Moebius, I believe that hysteria cannot be considered as the attribute of a people whose civilization is too refined, unless it be the expression of the decadent period of a people.

Empirically we find that certain classes of individuals possess mentalities which offer a favorable soil for the growth of hysteria. There are, on the one hand, the dwellers in rural communities, and on the other the workmen of the proletariat. At the present time it is among those coming from the country that one actually meets the purest types of hysterical conditions. There may still be found, from time to time, in some remote village, an epidemic of hysteria which recalls the classic instances of the kind described in the Middle Ages. We are all familiar with such instances.

I need only remind you of Kräpelin's researches among the natives of Java, where he found hysteria

extremely abundant; in fact it and dementia præcox were the most prevalent types of mental disorder.

Hysteria as seen clinically to-day is the morbid psychic reaction of choice in individuals of simple and naive minds who are transported into conditions of existence to which they find difficulty in adapting themselves. It has been held by many that emigration from the country to the city, by reason of the efforts at adaptation which are necessary to individuals, constitutes an important cause of modern hysteria, in which connection Gaupp's interesting comparisons of the psychoses in rural and urban communities are illuminating.

We have already seen the important rôle which social aspirations play in the hysteria of the proletariat workman, which Hellpach considers to-day as the same thing as the hysteria of the masses of the Middle Ages. "Hysteria is the ordinary response to the exigencies of life in all those people whose roots have been torn up, or who have been disenchanting with their ideas, but who still present the simplicity of psychic reaction of a child."

So much for that aspect of hysteria seen in its simplest phases as an expression of the naive childish type of mind still engrossed with the wonder working of Nature.

There is still another type which has often been written about, particularly by the French school, whereby hysteria is regarded only as a manifestation of mental degeneracy. There is no question that one may say that it is a manifestation of mental insufficiency. But this term "insufficiency" is by no means definite. One can only speak of the mental insufficiency of an individual in regard to the conditions under which such an individual is called upon to live. Mental insufficiency indicates disproportion between the mental aptitude of the individual and the demands imposed upon him by life. There is a mental weakness which may be purely physiological in itself as in the case of a child and to a certain degree in woman; in the same way such mental weakness may be the attribute of the average mentality of a race, of a people, and of a class. According to the external conditions this weakness will pass into insufficiency and will give rise to pathological manifestations such as hysteria.

Following Schnyder I have laid considerable stress upon that aspect of hysteria which may be called *evolutive*, forming, in fact, only an accident in the mental evolution of the individual or of the species. There remains to be discussed very briefly this second group developing not on a simple healthy soil, but on that of a distinct neuropathic heredity, a group which we have for some time termed the degenerative hysterias.

The degeneracy may lead the mentality toward an inferior type which it corresponds to in some particular, as the infantile type. The psychic change is often partial. It may, for example, allow brilliant intellectual faculties to exist along with a loss of the moral sense (superior deviate). It predisposes to hysteria when it diminishes in the individual the qualities of judgment and of rational criticism, permitting these individuals to flounder into psychoneuroses according to the degree in which the conditions of their existence are unfavorable to them. It is in this group that we find the

great disproportions in mental capacities. It is from this mixture that the demifous of the world are made.

To say that the hysterical forms of degeneracy are met with most often in the superior classes of modern society, in what might be called the bourgeois classes—the newly rich, or springing from those unions in which titles and dollars, or family and wealth make an uneven mixture, only details of course a fact of distribution. These forms more rarely present the characteristics of pure, out and out hysteria. The mental degeneracy asserts itself by combinations of hysterical symptoms, and by symptoms belonging to other psychopathological conditions. It is perhaps in this milieu that the purer types of Janet's psychasthenia are encountered.

Finally a word as to a third broad subdivision, not that these subdivisions are anything more than of the most general scope—we find the purely *symptomatic hysterias*. These have already been mentioned. They constitute one of the chief stumbling blocks in the path of psychotherapy. Picture one's attempts to try to reeducate a patient who is suffering from dementia præcox, with an accompanying symptomatic hysteria; or one in whom a carcinoma of the stomach, or a multiple sclerosis, or a tumor of the brain or spinal cord is overlooked. The case reported by Dr. W. A. Timme last year before this society of general spinal carcinosis which went the rounds of many of our members as a hysteria, is only one of many of this type, and I think that I am not unduly critical in holding the opinion that some opposition to psychotherapy is found in the minds of those who have thought it inefficacious in cases of this kind.

But to another phase of the problem of hysteria and of psychotherapy. Does hysteria constitute a morbid modification of mentality more frequently seen at the present time than formerly? What is the future of hysteria? Such questions interest both the physician and the psychologist.

It is very difficult to solve the first question by depending upon statistics, and almost impossible to bring them together upon the subject. However, I believe that the statistical study of hysteria permits us to state that certain forms of hysteria have diminished in frequency as the result of the progress of civilization. These are, first of all, the collective hysterias affecting a whole population, such as were described in the Middle Ages under the various names, saltatory epidemics; dancing manias; witchcraft; inquisitions, etc. Then the individual forms growing out of religious mysticism and the belief in spirits and demons. Manifestations of this kind are still seen to-day, but in a manner isolated and of a more benign character than hitherto. Whatever one may say of it the progress of education in the majority of civilized countries has made the limits of credulity recede. The superstitions of the rustic become more and more rare; but if naive credulity has lost ground, it has given way to those qualities of healthy logic and rational criticism which prevent the influence of false auto suggestions and erroneous conceptions of realities to rule the personality.

It we can believe that the mind of the masses is

becoming more and more free from the false doctrines of the past—from the manufactured ideals meant for the good of certain classes and imposed by all the power possible by these classes, call them religion, or politics, or socialism, or what not; if liberty of thought meets fewer obstacles, and more sympathy, even if the reach for happiness has taken on a more rugged character, social revindication and economic struggles constitute for the modern man an ever renewing source of moral disturbance.

Abandoning more and more the hope of future compensations, as preached by such moderns as Nietzsche, Ibsen, and others, man wishes to possess and to enjoy everything immediately. Impatience, irritability, immoderate ambitions, the idea that happiness consists only in accumulating material advantages, these are the disturbing features for the modern individual. It is not at all astonishing, therefore, that his nervousness bears the mark of these various influences, and is distinguished from a nervousness fed by characters which differ from those of former times. Modern nervousness is translated into neurasthenic or psychasthenic forms more than by purely hysterical forms. Hysterical conditions are still strongly impregnated by mysticism, imagination, fantasy, naivete, and puerility which belongs so to speak to the golden age of nervousness. Modern mentality in the upper levels of culture is more complicated; it lends to man an imagination which is less replete with ideals; it also leads to morbid manifestations which are more adequate to reality.

Hysteria still remains the appanage of primitive mentalities. It will still constitute, for a long time, the morbid manifestation of choice of the feminine mentality, which submits more easily than that of man to concerted influences. However, it is to be foreseen that the contemporary feminist movement, by exposing woman to social conditions analogous to that to which man is submitted, will make her share the risk of a common nervousness. In woman the neurasthenic conditions will tend to supplant hysterical conditions, and there are not wanting many who think this is so to-day.

I believe that the era of the grand manifestations of collective hysteria may be considered as closed. (The factors that have brought this about are beyond our present discussion.) Man possesses to-day in the face of causes of intellectual, political, and social oppression to false ideals means of reaction which he did not formerly possess. Liberty of the press, democratic political institutions, workmen's organizations permit him to manifest his discontent otherwise than by hysteria. These are the present day conversions for what in the past might show themselves in general hysteria. On the other hand, hysteria by reason of individual manifestation is not ready to disappear, for it would be rash to hope that the faculties of logical and rational criticism would so soon dominate the psychical activities of man.

The moral education of man still rests in a large degree on the principle of authority transmitted by the Church, it makes the practice of duty depend upon the fear of punishment and the hope of reward. It does not incite man to seek for pure and simple truth, or to disinterested culture of right;

it does not develop sufficiently his judgment or healthy logic, necessary qualities for the formation of a high moral conception of life. It is this last which will permit man to pursue with serenity the end which he proposes in life, without selfish pre-occupation and without discouragement; it is in this way that he will escape the depressing and dissolving action of the emotions, and that he will accept the inevitable with a healthy philosophy of life, and will not seek in the subterfuge of hysteria a remedy for his insufficiency, or a compensation for his disappointed hopes (Schnyder).

If I may here interpose a thought from Nietzsche which expresses this truth in another form. "Man's shame of man. The weary pessimistic look, the mistrust toward the riddle of life, the chilling No of the surfeit of life—these are not the symptoms of the most evil period of humanity. On the contrary, being swamp plants, they appear only when the swamp to which they belong has sprung into existence. By that I mean the sickly effeminacy and moralization by means of which the animal man is taught to feel ashamed at last of all his instincts. On the road to become an 'angel,' man (and particularly woman) has reared for himself that spoiled stomach and furred tongue, which rendered obnoxious to him not only all the pleasure and innocence of the animal, but made life itself of ill taste to him."

"A strong and well fashioned man will digest his experiences (including deeds and misdeeds) as he will his meals, even if he has to devour hard morsels. In case he fails to get beyond an experience this kind of indigestion is physiological no less than the other, and, in many cases, merely one of the consequences of the other." Nietzsche, *Genealogy of Morals*, p. 78.

As may be seen, we have arrived at a *moral conception of hysteria*, which seems to be the logical termination of a study which has for its object pathological manifestations of the mind which are most intimately bound up with the moral personality of man. If psychology is absolutely indispensable for the analysis of the mechanism of hysterical phenomena, and here we have full justification for those methods of study as outlined by Freud, Jung, Janet, and others, it cannot in itself alone resolve the complex problem of the origins of the hysterical modification of mentality. To all psychological conceptions of hysteria there must be associated a moral conception of it. It is chiefly this moral conception which ought to inspire all rational treatment of hysteria, such as has been indicated by Dubois in maintaining for the psychoneuroses a *moral treatment* in the highest sense of the word. The psychological analysis alone is but a step in the process toward reaching, from the therapeutic point of view, anything but partial results and the suppression of such and such symptoms. To get at hysteria in its very origin, one must penetrate more profoundly into the personality of the patient. He must be helped to reconstruct his mental synthesis on the basis of good logic, and to reconstruct his moral education, a complicated and often arduous task, but in Dubois's terms it is a true treatment of the soul which no physician could repudiate to-day.

## THE MEDICAL PROFESSION'S DUTY TO THE CHILDREN OF AMERICA.\*

By L. T. ROYSTER, M. D.,  
Norfolk, Va.

Looking back over history many changes are apparent. Nations have risen, waxed strong, prevailed over lesser peoples and disappeared; kings and rulers have appeared, triumphed for a space and passed away; war and pestilence have devastated the land, pauperized nations and crushed their rising hopes; all these are remembered to-day by a page in history and are relegated alike to a desolate immortality. Evil forces have not always prevailed, however, for there has been a more potent influence for good, and in the midst of gloom and despair the dawn has broken upon events notable for their uplifting influence on the human race and the improvement of health and morals.

No changes have been more marked, either in themselves or in their result, than those in the field of medicine. These changes have been quiet and unostentatious, characteristic of the lives of the men through whose efforts they have come to pass; men who lived lives of self sacrifice, poverty, and even persecution to serve their fellow creatures.

The evolution of medicine is peculiarly interesting. The incantations and gestures of the "medicine man" of the aboriginal tribes have given place to the assayed drugs of the modern pharmacopœia; the terrible carnage of epidemic pestilence has been checked by the simple application of isolation and quarantine; "laudable pus" has disappeared and in its stead we have a clean wound healing by first intention, as a result of cleanliness in the operating room; the ignorant and uncleanly "granny" has been supplanted by the trained obstetrical nurse, and yellow fever and malaria are fast disappearing through the destruction of the mosquito. Through the whole field of investigation, discovery, and improvement there has been a strong and marked tendency toward prevention and this is undoubtedly the keynote of modern medical endeavor.

But while the world has been gradually aroused to the importance of medical matters the most important part of the human race has been singularly neglected. I refer to the children, for only during the past fifteen years have they begun to receive their just proportion of our attention, and to them the physician owes his greatest duty. The affairs of the nation will soon rest on the shoulders of the children of to-day, and how many reach the years of maturity physically capable of coping with the problems which confront them? On whom rests the responsibility of improving the physical, mental, and moral being of the nation? Especially on the physician. Undoubtedly the greatest source of mortality among infants is ignorance in their handling, the correcting of which fact is obviously education, and who alone can supply the necessary instruction to overcome this evil? Manifestly the physician. How then can the physician best do his duty to the children of our nation?

First by educating himself and second by educating the public. Pediatrics should be taught as thoroughly in our medical colleges as is anatomy or

\* Address before the Faculty and Graduating Class of the University of North Carolina at Raleigh, N. C., February 22, 1908.

surgery, yet it is only within the past few years that this branch has been given any attention whatever as a separate course in the curriculum, with the result that men have graduated and become practising physicians knowing nothing concerning this class of patients, consequently these patients have been turned over to the tender mercies of old women and superstition, usually synonymous terms.

The study of pædiatrics is to-day in the class of specialties, and when we consider the fact that out of every one thousand children born into the world two hundred and thirty die during the first twelve months and 10 per cent. of the remainder before the end of the fifth year, does it not seem imperative that a larger proportion of our efforts should be directed to the prevention of this terrible loss to the race during infancy? To this end not only should pædiatrics be taught in the curriculum of our colleges by thoroughly capable pædiatrists, but no course of clinical medicine should be considered complete until a large amount of time shall have been devoted to the study of children. Not every practitioner is expected to acquire the knowledge of a specialist, but every physician licensed to-day must be expected to know enough about children to appreciate his limitations, and when he does this and is honest with his patients and himself he will seek competent advice, when needed, just as he does in surgery or conditions of the eye. Also in order that he may do his duty by the children in his practice he must know the right and wrong in handling them and so teach the parents that they in turn may do their duty.

Every hospital should be supplied with properly equipped children's wards where all conditions peculiar to this class of patients may be given the most approved treatment. In order that they may receive the best treatment the convalescent ward must be distinct from the sick ward, in order that the little patients may be removed from depressing surroundings and be given an opportunity to express their feelings in play and laughter, signs of returning health.

One of the most important matters concerning children which demand the attention of the profession is the "secret nostrum" evil, which has become not only a blot on our civilization, but is a menace to health and even life. I believe that the administration of such substances is responsible for more deaths than we realize, and it is imperative that some definite measures be adopted which will control the distribution of such nostrums and the criminally false statements asserted for them through the medium of clever commercial advertising. If legislation can accomplish nothing, and it seems that it cannot, then the profession must educate the public among whom it moves as to the certain result of relying on the supposed benefit to be derived from the use of articles absurdly alleged to be cures, and that a compound which may do no positive harm may by delay place the patient beyond the aid of intelligent treatment. It seems that something might be done to prevent such quackery from affecting innocent children at least.

And just here a word may be pertinent concerning the so called "ethical proprietaries." These may be made just as dangerous as the secret nostrum if the statements of the manufacturers as to their scope and power are not curtailed. The use of these preparations arises from two sources: First, the parents themselves get into the habit of prescribing for their children in accordance with the printed circular, and the second, which I am ashamed, almost, to admit, through the indifference and ignorance of the profession itself. Physicians not knowing a great deal about children are only too apt themselves to accept the statements of the circular of information and prescribe in original packages—as they are always advised by the manufacturer to do—some proprietary preparation, or to advise the mother to give the baby this or that cough mixture or prepared food. Is it not time to call a halt?

Unfortunately, maternal feeding in this country is fearfully on the decrease and we all know that there is no true substitute for mother's milk, but when the necessity for artificial feeding does arise the greatest care and study on the part of both parent and physician are absolutely essential to success. As cooperation on the part of the mother is necessary, it is our duty to instruct her carefully as to the nature of feeding, the care necessary in the preparation of the meal, and the scrupulous cleanliness which is essential in the handling of milk and utensils, and on these points the average physician is in many instances in as great need of having his attention called to these things as the mother. The busy practitioner with little time at his disposal is too apt to overlook details and to fail to examine the conditions surrounding the child, the character of the stools, the sources from which milk and water are being secured, and the necessities of the individual child. Rules and formulas have been set forth from time to time which are said to overcome the various difficulties of infant feeding. Each discovery or improvement has met with marked success for a while only to fail in some difficult case. All of these various ideas, however, have served their purpose and will ultimately result in a treatment based on rational application of well understood conditions and principles.

The greatest number of failures must be accounted to the fact that we too often lose sight of the individuality of the patient. It is just as true of children as of any other patient that what is one's food is another's poison. When we are not succeeding in an individual case we are too prone to shift responsibility, and unfortunately this is usually done by telling the mother to administer some commercial preparation "guaranteed to suit any case" by following the directions of the circular. Thus the mother is left helpless to rely upon her own uneducated judgment, and the child finally becomes a monkey faced marantic or a fat, rickety or scorbutic wreck; if it does not die. Is this doing our duty by this class of patients? If the physician has not the time to study the difficult cases in his practice, he must do the best he can by his charge and consult one who possesses special knowledge on the subject, just as he would turn over to the surgeon a case of gall-stone or brain abscess. I have yet to meet with a case of feeding which was not

From a manuscript on "Secret Nostrums," by Dr. Royster, and sent to the editor of the *Journal of the American Medical Association*, both American and foreign.

amenable to treatment by properly modified cows' milk. Hence I do not consider the prepared foods of commerce a necessity. Few communities are as yet supplied with up to date laboratories for the scientific and approved preparation of milk formulas, so in most instances the mother must be instructed in this preparation, which as a rule can be done very well, and some of my very best results have been obtained under such circumstances.

An intelligent mother is as great an aid to the physician as the ignorant one is a drawback, hence the importance of the physician personally instructing the mothers of his patients. In doing this we have not only the most important but the most difficult part of our task. As before suggested, ignorance and superstition have played so important a part in the handling of infants that their influence is difficult to overcome. The idea that a teething child must necessarily have green and undigested stools or "inward fevers" is just as erroneous and absurd as the "sun do move" theory, and the fact that milk in some form of modification must form the sole article of diet during the first year of life cannot be too forcibly impressed on the public mind, and a matter of just as great importance is that every child artificially fed must at all times be under the care of a physician.

The improvement and maintaining of a proper milk supply of a community should be the constant care of the medical profession, and in order that this as well as all matters pertaining to the welfare of children be properly attended to, this profession should be represented on all controlling boards.

The value of fresh air in the treatment of all ailments of children as well as its influence on the healthy child cannot be too strongly emphasized. It is not sufficient that the little ones have a daily outing; as near as possible the growing child should live out of doors. High winds and damp atmosphere must, it is true, be avoided, but aside from these two conditions we need not fear the result of outdoor life. The best tonic for a physically subnormal child is fresh air and sunshine. I have repeatedly seen a child that did not seem to be improving on what appeared to be a proper milk formula at once pick up and gain steadily when sent out of doors for the greater part of the time. The old superstition that a sick child must not be exposed to the atmosphere of outdoors is deeply rooted in the popular mind, and we frequently see the room in which a sick child is lying close and stuffy to the point of suffocation. I am now following an almost universal rule in using all the fresh air compatible with the condition of the individual case.

The school children of to-day are in vastly greater need of our attention than those of former times. The strenuous life reflects itself on the school child; further, it has extended itself into the very school room. The temptation to overcrowd the child with multitudinous duties and studies is great. The standard of the grades is constantly being raised, even though the children are probably less prepared physically than they were a generation ago. The question is repeatedly asked why so many men of prominence come from the rural districts; the answer is plain. The quiet life of the country or small town better prepares the nervous system

for the battle before it, while the active and irregular city life produces young adults with already wasted energies almost devoid of that poise of development which is so necessary in a calling of any kind. The old saying, "early to bed, early to rise," etc., is to-day considered a relic of medievalism and is too often laughed at as being out of date, but if the average American mother would pay personal attention to her offspring and not leave them to develop along lines of their own choosing rather than those which are for their good, and not spend so much time and thought in getting them into society, or having them taught "accomplishments" which are really drawbacks to their physical and moral development, and dwell more on matters which tend to develop character and health, we would have as a result the sturdy manhood and womanhood for which in this age the need is so great.

The choreic school child is an object of pity, and the one who is suffering from adenoid vegetations is noticeable at sight and is incapable of mental activity, but nevertheless these creatures are forced beyond their strength to keep up with a grade too advanced for them. From such as these as well as those suffering from eyestrain come many of our laggards and defectives. These children are often kept back in their class and in turn keep the class from advancing, yet most of this could have been overcome or prevented had the family physician observed more carefully the children in his practice and advised the proper measure of treatment in the individual case. All children classed as backward should be given the benefit of a thorough medical examination and all physical defects corrected. Eyestrain should be relieved and adenoids removed, and by this procedure a large percentage of such children will soon be among the average of their class, if not at the head. It is surprising how much the mentality of children is affected by physical defects. The results of treatment in this direction are little short of astonishing, as is clearly proven by the report of the recent "adenoid crusade" of New York city. Those children whose defection is truly mental can be vastly improved in special classes and schools devoted entirely to their instruction, where the difficulties of individual cases may be met and overcome by proper training directed to personal needs.

The fearful and shameful results of ophthalmia neonatorum demand our most careful consideration and the most stringent laws should be adopted and enforced in all States, requiring prophylaxis at birth by careful attention to the hygiene of the eyes of the infant. The neglectful physician is, in large measure, responsible for the baneful result in this condition.

No discussion of this nature would be complete without at least a reference to the inexorable law of heredity. This law hangs over us as a dark shadow and cannot be brushed aside, and until the time arrives when national eugenics become more than a theory the duty of correcting the evils incident thereto lies largely at the door of the physician. The care of the pregnant woman and prophylaxis regarding venereal disease is the duty you owe the generations yet unborn. The opportunity afforded the family physician in uplifting the human race

is one which you should appreciate and grasp and utilize, and in this way better than in any other can you be benefactors to humanity. As I have already said, the health and morals of a nation are always complementary, and the mothers of the land are the powerful agency through which we must accomplish the greatest good. Mothers are the directors of the lives and conduct of their offspring, and from them should come the proper instruction of the children, but from the medical profession must come the instruction for the mother.

The mothers of this country are in appalling need of instruction in the rearing of their children; they must be taught how to feed them; that, as has been said, milk in some form of modification is the only food necessary during the first year of life, and that any other substance during this period is not only harmful, but exceedingly dangerous. That few artificially fed children can digest whole milk even at the twelfth month, hence the weaker formulas increased in total quantity are far better as a rule and more easily digested than the smaller amount of a strong solution. That the lunch of the school child is more important than the home meal, and that its preparation should be attended to with great care. That sweets should form a very limited proportion of the diet of the growing organism, and that fancy dishes should give place to plain but wholesome food.

The mother must be taught also how to direct the child's exercise. This should be as far as possible in the open air and always of a definite character and preferably with a certain amount of system. The associates of children should be carefully watched, and here the whole responsibility must rest on the mother, but the physician must tell her why this is of importance in protecting the morals of the child, as the wrong sort of companions may impart a very erroneous impression of right and wrong. Above all, the mother must be told how to inform the child who is about to change from youth to young but mature physical adult life, about matters pertaining to sex, on a correct understanding of which and on the proper care along these lines depends the protection of the race from the dread results of venereal disease, for one single misstep may result in the acquirement of syphilis and the ultimate production of that pitiable object, a luetic offspring. These matters must be taught by the mother, who, above all, should be the one to instruct the children, and the mother in turn should learn them from the family physician. I repeat, therefore, unhesitatingly, that the medical profession has it within its opportunity to be the greatest factor in the uplift of the nation.

Young men of the graduating class resolve, therefore, in leaving your alma mater that you will be of service to your fellow men; that you will be a force to uplift the fallen, to cheer the despondent, and, above all, to benefit the race; and to this latter end heed the cry of the children who come under your care, for upon them depends the future of our country and the human race; give the humblest child whose habitation is a cottage the same gentle, painstaking care you give the more favored one whose dwelling is a palace, for upon a physician such as

this was passed the encomium of the great philosopher who said:

"But nothing is more estimable than a physician who, having studied nature from his youth, knows the properties of the human body, the diseases that assail it, the remedies that will benefit it, exercises his art with caution, and pays equal attention to the rich and the poor."

TAYLOR BUILDING.

#### THE ASSOCIATION OF TUBERCULOSIS OF THE LUNGS WITH DIABETES MELLITUS.\*

BY HENRY L. SHIVELY, M. D.,  
New York.

For two diseases so essentially different in their nature as are pulmonary tuberculosis and diabetes mellitus, there are certain points of analogy between them which are at once curious and striking. Diabetes is to be considered a typical example of a disease of metabolism, of disturbed function due to the action of unknown toxins originating within the body itself. The production of these toxins is apparently related in some way to the internal secretion of the islands of Langerhans, and there is accumulating evidence, for which we are largely indebted to the investigations of von Mering and Minkowski and the recent researches of Hanseman, Opis, Herter, and Bosanquet, that the pathological basis of true diabetes is a congenital or acquired insufficiency of these histological elements of the pancreas. Hanseman found the pancreas diseased in seventy per cent. of all of his cases which came to autopsy. In nineteen cases Opis showed the gland to be affected in fifteen, Bosanquet in seventeen out of nineteen cases.

Tuberculosis of the lungs is perhaps the best known and most carefully studied example of a chronic, infectious disease due to a specific micro-organism introduced from without the body. Both diseases are usually progressive in their course and are regularly attended by emaciation; in both there is impairment of the power to utilize carbohydrate food; both diseases are very fatal in early life, and are, on the other hand, comparatively well withstood when they appear after middle age. Both have strong racial affinities. The negro and Irishman, who are extremely susceptible to tuberculosis, are less so than most races to diabetes. Statistics of the Johns Hopkins Hospital show that the negro in Baltimore has only half the susceptibility to diabetes of the general white population. In Ireland the mortality from diabetes is three per 100,000, as compared with seven in 100,000 for England, and five in 100,000 for the whole of Europe. The Jew, who is generally believed to be especially resistant to tuberculosis and in whom the disease certainly often takes a more favorable course than in other nationalities, is singularly prone to diabetes, as are likewise the French and the native populations of India, especially the Hindus. In Paris the mortality from diabetes is fourteen per 100,000. Von Noorden states that at Frankfurt the deaths from diabetes among Jews are more than six times the

\*Read before the West End Medical Society, Feb. 17, 1908, and before the Section on Medicine at the New York Academy of Medicine, April 11, 1908.

proportion among non-Jews. Bouchardat considers the frequency of diabetes among Hebrews to be due to their fondness for sedentary occupations and disinclination for physical exercise. Von Noorden advances the theory that it is due to a physical degeneracy produced by many centuries of inbreeding. Both tuberculosis and diabetes are more common in cities than in the country, and in both hereditary predisposition is of some account in the etiology. Fitz and Joslin found heredity to play a role in 23.8 per cent. of their cases of diabetes, Naunyn in seventeen per cent. of the cases reported by him, Bouchard in twenty-five per cent., and von Noorden in 18.5 per cent. It has even been suggested that under some circumstances diabetes, like tuberculosis, may be communicable, as in the so called cases of conjugal diabetes reported by Reil and Henke, Oppler, Külz, Schmitz, and others. Naunyn agrees with Senator, however, that these cases are to be explained as coincidences. In both diseases drug treatment is of relatively little value, as compared with the importance of detailed attention to hygiene and diet, and the intelligent cooperation of the patient himself is vitally necessary for any measure of success in either. The prognosis in both is largely dependent upon the social and financial status of the patient, the unfavorable influence of poverty, ignorance, and bad hygienic conditions being most marked. Both diseases exercise a decided effect upon the psychical attitude and morale of the patient. The tendency of the diabetic is to melancholy and a peevish hypochondria. The consumptive, on the other hand, frequently exhibits a blind and fatuous optimism. Finally, both tuberculosis and diabetes are often associated in the same person.

This association has long been a familiar clinical fact. It was first noted in literature by Richard Morton in 1606, his Latin treatise, entitled *Phthisiologia*, containing a chapter *De Tabæ a Diabete*. Diabetic phthisis was more fully studied by John Rollo in 1798. Bardsley asserts that all diabetics are attacked with tuberculosis in the latter stages of their disease. Griesinger found tuberculosis to be present in forty-three per cent. of the 250 cases reported by him. Bouchardat found pulmonary tuberculosis nineteen times in nineteen autopsies. Some of the latter authorities give a less proportion. Thus Germain Sée states that only twenty-three per cent. of diabetics die tuberculous. Naunyn in fifty autopsies found tuberculosis in forty-one per cent. Frerichs found the lungs tuberculous in twenty-five out of fifty autopsies. In most cases the tuberculosis is secondary to the diabetes, but this is not invariably the case. The tissues of the diabetic, which are so vulnerable to eczemas, carbuncles, ulceration of the skin and mucous membranes, furunculosis, and gangrene show also a peculiar susceptibility to tuberculous infection. Bouchardat believed that the polyuria of diabetes created a predisposition to tuberculosis in much the same way as does the prolonged lactation of milk cows and nursing mothers who bear numerous children in quick succession. The tuberculous tendency of diabetics is now, however, very generally considered to be due to the hyperglycemia and hyperglycosis of their tissues, for it is well known that the tubercle bacillus has a sweet tooth, Nocard and

Roux having demonstrated that it is common with many other microorganisms develops most luxuriantly in a culture medium to which sugar has been added.

Before the tubercle bacillus was known diabetic phthisis was often described as a disease *sui generis*, but soon after Koch's discovery Immermann and Rüttimeyer demonstrated that the tubercle bacilli are regularly present. There are, however, certain peculiarities in the pathological conditions present in the lungs in tuberculosis accompanying diabetes, which have been well described by Naunyn. The tuberculous cheesy infiltration is soft, and there is a tendency to the rapid formation of vomice, masses of tuberculous tissue surrounded by a puriform fluid being found in the recent cavities. Some authorities still consider that in diabetes there may be a destructive lesion of the lungs closely simulating tuberculosis without the presence of tubercle bacilli. Such a case has been reported by Roque. Von Noorden is authority for the observation that there frequently exists in the sputum of diabetics a substance which rapidly disintegrates and destroys the tubercle bacillus. Among the curiosities of the literature on the pathology of diabetic tuberculosis is a case reported by Schindelka of a diabetic dog with a complicating tuberculosis of the lungs. Examples of a similar association have been observed in apes.

In view of the emphasis which has been attached in recent years to the pancreatic origin of diabetes it might be surmised perhaps that in the exceptional cases in which tuberculosis precedes the development of diabetes there might be found a tuberculous lesion of the pancreas as a cause of the latter disease. Such, however, is not the case. Kudrewetsky found in a series of 128 cases of tuberculosis of the lungs the pancreas was affected but fifteen times, and in these cases diabetes is not noted as having been present during life. Primary tuberculosis of the pancreas, if it exists at all, is certainly extremely rare. Delafield and Prudden do not mention it as occurring. Cornet says that tuberculosis of the pancreas is always secondary. The only cases referred to in literature are two cited by Senn, one of which was reported by Wilson in 1829, the other by Aran in 1846. Both of these cases antedated a time when any very exact or certain determination of the tuberculous nature of the lesions was possible, and in neither case was diabetes present. The usual lesions of the pancreas in diabetes are an interstitial pancreatitis, atrophy of the glands, a diffuse arteriosclerosis, or a hyaline degeneration of the cells of the islands of Langerhans. Tuberculosis as a cause of diabetes may then be dismissed.

Frequent as is the association of the two diseases, one or the other in its early stages is not infrequently overlooked. It is a safe rule in practice to make repeated examinations of the chest in diabetics, and in tuberculosis the urine should be periodically examined for glucose. Tuberculosis of the lungs in diabetics, especially of the obese type, frequently runs an atypical course. There is often observed a somewhat characteristic, reddish cyanosis of the face instead of the ordinary pallor or hectic flush of tuberculosis. The cough is often slight

and attended by little or no expectoration. Sugar may sometimes be demonstrated in the sputum, and the pulmonary lesion may terminate in gangrene, which is not attended by the characteristic fetor of ordinary gangrene of the lungs. The appetite is usually well preserved and may even be greater than in health. The temperature may not be elevated, and night sweats are often not present. Seegen and von Leyden state that hæmorrhages are of rare occurrence, on account of the higher specific gravity and greater viscosity of the blood. Dieulafoy, however, does not consider hæmorrhages infrequent in diabetic consumptives. On the other hand, if the tuberculosis is the prominent feature, the diabetes may escape recognition. It has been frequently observed where phthisis develops in a subject of diabetes there may be a marked diminution in the quantity of urine and the percentage of sugar will fall. These changes, however, are delusive signs of improvement. The diabetes continues unchecked, and is hastened in its progress by the complicating tuberculosis. In the later stages the dry itching skin of the diabetic becomes moist and there may be profuse night sweats.

Gouty diabetics are said to seldom develop tuberculosis. Rénon has reported at least one such case, however, and others have been described by Charcot, Brouardel, and Naunyn. Diabetics who neglect their diet and thus invite an access of glycosuria are more likely to become tuberculous than careful, conscientious patients who observe a strict regimen.

The recognition of the coexistence of diabetes and tuberculosis has an important bearing upon the prognosis and treatment of the patient. Not infrequently in examining tuberculous patients, cases are discovered to be diabetic who have had no instruction as to diet and who have been receiving a syrupy cough mixture and cod liver oil with extract of malt, the latter consisting of more than fifty per cent. maltose, which is immediately converted into grape sugar in the intestine. Some of these patients are found also to have a marked acidosis, evidenced by the presence of acetone, diacetic acid and beta oxybutyric acid, with an excess of ammonia in the urine. The presence of these acetone bodies, which are to be regarded as a forerunner of the danger of coma, makes it a question of more than theoretical interest whether the administration of large quantities of oils and fats, which is an important part of the dietetic treatment of tuberculosis, may not possibly in some cases hasten a fatal termination in diabetic coma. Magnus Levy has shown that beta oxybutyric acid is in part at least derived from fats, and this is the parent substance of the other acetone bodies, diacetic acid and acetone, into which it is readily changed. In this connection the experimental evidence of Grube is interesting, that pork fat is peculiar in not being a source of beta oxybutyric acid. It could seem practical wisdom in cases showing strong reactions, with the ferric chloride and sodium nitroprusside tests with high dextrose percentage in the urine, to limit the quantity of butter, cream, and oils, with the possible exception of pork fat, and substitute for such tuberculous diabetics alcohol, which Atwater and Benedict have shown may take the place of

fats and carbohydrates as a source of energy, and thus spare, in a measure, the excessive tissue waste which is a conspicuous symptom of both diabetes and tuberculosis. The combustion equivalent of alcohol is seven calories, of fat 9.3 calories, and of sugar four calories. Another indication for the administration of alcohol in diabetes is the presence of acetone substances in the urine. Langstein and von Noorden agree that the effect of alcohol is to diminish acetonuria, and patients taking alcohol in moderate amount show no increase in the sugar content of the urine. The quantity should not exceed two ounces daily, in the form of pure whisky, gin, cognac, or a dry wine. A rational therapy in the acidosis of diabetes also demands an additional allowance of carbohydrate food and the exhibition of alkalies to overcome the diminished alkalinity of the blood. An excessive flesh diet is also considered to be favorable to the acid intoxication which is believed to be a factor in producing diabetic coma. The difficulties in the prevention and treatment of this grave condition are thus apparent.

These difficulties are not diminished by the fact the von Noorden and other are now inclined to doubt the entire theory of acidosis as promulgated by Stadelmann and Naunyn. For those who believe that the acid toxæmia of the acetone substances is adequate to account for the phenomena of diabetic coma, theoretically, all classes of food are more or less contraindicated, carbohydrates on account of their failure to be oxidized and their excretion as sugar, fats on account of their splitting up into fatty acids, and proteids because in excess they also produce acidosis. The only escape from this blind alley is to treat the patient without too much regard for theory. No abstract considerations should determine the diet. The patient's tolerance for carbohydrates must, in every case, be carefully established, and as liberal and varied a diet permitted as is possible. It is better for the patient to gain in weight and improve in health with an increased percentage of sugar than to lose ground with a reduction in the glucose content of the urine. The case is even more difficult with a complicating tuberculosis present. Some authorities advise ignoring the diabetes and treating only the tuberculosis. Dieulafoy in these cases excludes only sugar from the diet. Naunyn has shown, however, that great benefit may be derived by the tuberculous patient with diabetes from a carefully regulated diet. Fortunately many of the indications for treatment are the same for both diseases. A diet of meat, fat, cheese, and eggs is equally good for both. Milk may often be permitted for diabetics, especially when sour or artificially fermented. The drug of greatest value in diabetes, opium, with its derivatives, codeine and heroin, is also indicated for the cough, the hæmorrhages, the diarrhæas, and to promote the euphoria of the advanced consumptive. The diabetic consumptive is very often afebrile, and for such cases exercise in moderation in the fresh air is not contraindicated. Such exercise is distinctly useful for the diabetic, as it has been shown that larger quantities of carbohydrates are tolerated on account of the increased consumption of sugar by the muscles during exercise. Creosote and guaiacol carbonate, which have

continued in favor for tuberculosis, are also believed to relieve the symptoms of diabetes, notably the thirst and polyuria. Arsenic and strychnine, which have their advocates in diabetes, are good systemic tonics for the consumptive. Hydrotherapeutics are valuable in both diseases, as are also the alkaline mineral waters, woolen clothing next the skin, abstinence from tobacco, freedom from worry and care, and a quiet life in the country in a mild, dry, and equable climate.
